Cobalt.—It is not probable that there will be friction between the operators and the miners' union this spring. The nine hour shift will be considered seriously by both sides.

The high grade ore of the O'Brien mine is being shipped to Deloro.

The first carload of 30 tons of high grade concentrates and ore has been shipped from the Coniagas mine to the Thorold smelter.

The City of Cobalt Mine has arranged to ship two cars of low grade ore to Trail, B.C.

BRITISH COLUMBIA.

Victoria.—Official notice was given in the British Columbia Provincial Gazette of the last week of March that a section of Moresby Island is reserved for Government purposes. The notice read thus: Notice is hereby given that the following described tract of land, situated on Moresby Island, Queen Charlotte group, is reserved for Government purposes: Commencing at a point at the southwest corner of Harriet harbor, Skincuttel Inlent, Moresby Island; thence south 40 chains; thence east 60 chains; thence north 160 chains; thence west to the shore; thence southerly following the shore line to the point of commencement. The area reserved is close to the Ikeda and the Swede mines. It is supposedly well-mineralized.

Vancouver.—The Tyee smelter has taken an option on the Leckie group of claims on Moresby Island.

Nelson.—In the week ended March 28th the War Eagle mine shipped 850 tons of ore, averaging $42 per ton. Of this amount 200 tons came from the 11 foot or deepest level in the mine. This ore averaged $55 in gold to the ton.

Official announcement is made that the Granby Consolidated Company will expend $200,000 in enlarging and improving its smelting plant at Grand Forks, B.C. The ore and coke bunkers just completed are included in the appropriation. The other improvements to be made this year will give the works a capacity of 4,500 tons a day.

Rossland.—Deep mining is to be a feature of the Centre Star and its allied mines. The main shaft is to be deepened from the fourteenth to the sixteenth level, which will give a total depth on the dip of the ledge of about 2,400 feet. This depth should bring the workings down to the permanent water line, where it is thought by prominent mining experts there will be a considerable change for the better in the ore deposits. It is thought that the mines here, should the ore prove fairly rich at depth, can be mined at a profit to a depth of 5,000 or 5,500 feet. There is not much water to contend with, which is an important consideration, as it costs considerable to keep the water pumped from the workings of wet mines. Good ore is being met with on the lower levels of both the Centre Star and War Eagle of late, which greatly encourages the management. The ore body on the Blue Bird has widened out to

four and a half feet. The ledge is strong and well defined. This is the most important find that has been made in the south belt for a good many years. A steam drill has been installed, and, as there was a boiler on the property, the development work and the extraction of ore can be done with more speed and less expense than when the work was all done by hand.

CRANBROOK.—The Sullivan smelter at Marysville and the mine equipment at Kimberley have been seized by Deputy Sheriff Morris. Two executions for $861 and $785 respectively have been issued. A writ also has been served for $7,000 at the suit of the Crow's Nest Pass Company for coal and coke supplied during the past few months.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The Stavely Coal & Iron Company, Derbyshire, have just had their new Devonshire works completed at a cost of £300,000. The plant consists mainly of blast furnaces, built on the latest principle.

South Wales has made a new record for coal production, the figures for 1907 approximating 50,000,000 tons. The most remarkable growth has been in the output of anthracite in the Glamorganshire district.

The rescue station and experimental gallery erected by the Lancashire and Cheshire Coal Association at Howe Bridge, Atherton, for the collieries in the Bolton and Wigan districts was officially opened on the 2nd inst.

NORWAY.

The owners of the old Ranen lead and silver mines have concluded an arrangement with the Compagnie Laval to exploit a new process for zinc. A number of cyclone furnaces are to be built at these mines to obtain zinc oxide, and also an electric furnace at Trondjem, or some other suitable point.

The Hassel iron mines at Skotselven, which have not been worked since 1854, are to be started again.

FRANCE.

The Central Committee of French Collieries has placed at the disposal of the Commission appointed to investigate mine explosions a firedamp experiment station at the Lievin mines with an experimental gallery. Another experiment station is to be built in the Pas-de-Calais for testing and repairing rescue apparatus.

AUSTRIA.

Coal said to be of excellent quality has been discovered in the Vorarlberg, near Bregenz, and favorable results have attended the sinking of bore holes at Orleau.

BELGIUM.

The output of pig iron during the first two months of 1908 was 235,360 tons, as compared with 236,860 for the corresponding months of last year.

AUSTRALASIA.

Several large outcrops of copper ore have been discovered between Jingellic and Ournie, New South Wales, on the western slope of the range overlooking the Murray river.

The granulation plants erected by the Minerals Separation Company at the Central mine, Broken Hill, New South Wales, with a capacity of 3,000 tons of tailings weekly, have started work on a dump of 300,000 tons.

The Cobar gold mines, Fort Bourke, New South Wales, which have been idle for some years, have resumed crushing operations. The Elmore concentrating process for treating refractory ores is being installed.

SOUTH AFRICA.

The Transvaal Government has increased the amount of prizes to be awarded for the stope drill contest in 1909 under actual mining conditions, so that it will be possible for the winner to gain £4,000. It is proposed that the test be continued for some four months.

Six months' work on the tin mine of the Transvaal Government on the Zaaiplaats farm is regarded as having proved the value of the tin fields in the Potgeitersrut district. A four foot reef has been struck and traced for 250 yards and is stated to assay 30 per cent. tin. On the neighboring farms a number of men are working with good results.

Native labor is stated to be more plentiful than at any time in the history of the Rand. There has been a large influx, owing to the general depression and the cessation of public works throughout South Africa.

There is a continuous increase in the number of gold properties in Rhodesia operated by small workers, owing to the policy of the Butish South Africa Company in making them advances for the purchase of machinery. In January there were 175 of these mines at work.

UNITED STATES.

Bituminous coal miners to the number of about 250,000 men in the Middle and Western States went on strike on the 1st inst. on account of the failure of the United Mine Workers and the mine operators to agree upon a wage scale. A conference between the employers and men of the central mining field, including Illinois, Indiana, Ohio and Western Pennsylvania, was arranged to be held at Toledo, Ohio, on the 15th inst. to effect a settlement.

About 70 miners lost their lives by two explosions on the afternoon and night of March 28th in a mine of the Union Pacific Coal Company at Hanna, Wyoming. The first explosion killed 18, the other victims being a party of rescuers under Mine Inspector D. M. Elle.

A deposit of barite near Cartersville, Georgia, is being mined on a large scale.

The Copper Queen Company of Cochise County, Arizona, produced approximately 7,000,000 pounds of copper from eight furnaces in February.

MEXICO.

The Anglo-Mexican Mining & Exploration Company, with $650,000 capital, has started work on the Justicia group of mines in Jalisco.

The smelting plant of the Greene-Cananea Copper Company has been thoroughly renovated and nearly 1,000 men are now employed.

Mr. John Hayes Hammond has become interested in a project to develop the Laduz group of mines in Guanajuato, and a large company, capitalized at several millions, will shortly be organized. It is proposed to erect a reduction plant with the usual capacity of 1,000 tons per day.

STATISTICS AND RETURNS.

STATEMENT OF BOUNTIES PAID ON IRON AND STEEL DURING THE CALENDAR YEAR 1907.

	Pig Iron.	Steel.
Dominion Iron & Steel Co., Ltd.	$313,573.42	$497,212.07
Hamilton Iron & Steel Co., Ltd.	121,422.26	102,124.04

Totals	$793,005.27	$1,099.873.37

CORRECTION.

The Crow's Nest Pass Coal Company's output. The item on page 124 of the Journal should have read thus:—

Coal in 1907	981,939
Coal in 1906	806,901
Coke in 1907	231,368
Coke in 1906	213,295

The output of the collieries of the Crow's Nest Pass Coal Company for the week ending March 21st was 18,458 tons, or a daily average of 3,076 tons. For the corresponding week of last year the output was 20,674 tons, a daily average of 3,445 tons.

The output of the collieries of the Crow's Nest Coal Company for the week ended March 27th was 15,688 tons, or a daily average of 2,615 tons. For the corresponding week of last year the output was 20,434 tons, a daily average of 3,406 tons.

The output of the collieries of the Crow's Nest Pass Coal Company for the week ended April 5th was 19,687 tons, a daily average of 3,281 tons. For the corresponding week of last year the output was 18,970 tons, a daily average of 3,162 tons.

For the month of March the output of coal in the three collieries of the Nova Scotia Steel & Coal Company was another record-breaker.

The new No. 4 colliery is not included in the figures given, as it is practically idle while new electric machinery and equipment is being installed.

	Tons.
No. 1	23,124
No. 3	26,635
No. 3	7,645

This gives a total of 57,404 tons, which is an increase over last month, with No. 4 colliery included, of 4,604 tons.

The same activity prevailed at the steel plant, there being 6,200 tons of iron turned out, coke 8,592 tons, and steel 7,200 tons, which is about 2,000 tons more than for the month of February.

DOMINION COAL COMPANY'S OUTPUT FOR MARCH, 1908

No. 1 colliery	50,101
No. 2 colliery	69,494
No. 3 colliery	34,057
No. 4 colliery	44,997
No. 5 colliery	53,059
No. 6 colliery	21,849
No. 7 colliery	7,038
No. 8 colliery	15,916
No. 9 colilery	34,140
No. 10 colliery	13,478
	344,129

Shipments from the collieries of the Cumberland Railway & Coal Company, Springhill, N.S., for the month of February were 35,400 tons; for March, 38,656 tons.

NEW LISKEARD ORE STATEMENT.

Week Ending March 21st, 1908.

March 17th, Casey Mining Company, to R. C. Farrell & Company, Glasgow, Scotland, 40,000 pounds.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:—

	Week end Mar. 21 Ore in lbs.	Since Jan. 1 Ore in lbs.
Buffalo	65,700	409,540
Kerr Lake	63,080	207,370
La Rose	140,000	707,732
Nipissing	63,230	820,170
Nancy Helen	80,420	80,420
O'Brien	252,410	1,325,040
Silver Queen	60,000	356,700
Townsite	40,000	85,100
Temiskaming	61,420	238,536

The total shipments for the week were 826,260 pounds, or 413 tons.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:—

	Week end Mar. 21. Ore in lbs.	Since Jan. 1 Ore in lbs.
Coniagas	61,340	322,210
Cobalt Lake	64,310	186,610
City of Cobalt	127,970	228,080
Kerr Lake	63,010	270,380
La Rose	140,000	847,732
McKinley	61,900	757,980
Nipissing	63,320	820,170
Temiskaming	121,600	237,210
Trethewey	66,020	304,556

The total shipments for the week were 706,350 pounds, or 353 tons.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:—

	Week end April 4 Ore in lbs.	Since Jan. 1 Ore in lbs.
Buffalo	62,780	472,320
Coniagas	58,700	380,910
Cobalt Lake	.....	180,610
Cobalt Central	.....	49,700
City Cobalt	.....	288,080
Drummond	.....	92,340
Foster	.....	168,600
Kerr Lake	.....	270,380
King Edward	.....	127,240
La Rose	238,820	1,086,552
McKinley	80,640	838,620
Nipissing	80,000	900,170
Nova Scotia	.....	80,790
Nancy Helen	60,000	140,420
O'Brien	59,280	1,384,320
Right of Way	.....	60,210
Provincial	93,210	143,210
Standard	.....	39,730
Silver Queen	123,500	480,200
Silver Cliff	.....	52,000
Silver Leaf	.....	62,000
Townsite	.....	85,100
Temiskaming & H. B.	.....	318,000
Temiskaming	.....	237,250
Trethewey	182,560	487,110
Watts	.....	114,430

The total shipments for the week were 1,039,530 pounds, or 519 tons. The total shipments from January 1 to date are 8,915,248 pounds, or 4457 tons. The total shipments for the year 1907 were 28,081,010 pounds, or 14,040 tons, valued at $6,000,000. In 1904 the camp produced 158 tons, valued at $130,217; in 1905, 2144 tons, valued at $1,473,196; in 1906, 5129 tons, valued at $3,900,000.

SHIPMENTS FROM THE COBALT DISTRICT FOR THE MONTH OF MARCH, 1908.

Mine.	Tons of 2,000 lbs.
Buffalo mines	53.35
1. Casey Mountain	20.00
City of Cobalt	60.97
2. Cobalt Lake	30.76
Cobalt Central	24.85
Coniagas	93.30
Kerr Lake	92.73
King Edward	25.90
La Rose	398.37
McKinley-Darragh	121.33
Nancy Helen	69.52
3. Nipissing	125.93
Nova Scotia	20.00
O'Brien	258.78
Provincial mine	24.60
Right of Way	29.35
Silver Queen	19.59
Temiskaming	56.12
Temiskaming & Hudson Bay	36.15
Townsite Mining Company	20.56
Trethewey	153.11
Total	1,835.27

This was shipped as follows:—

Canada, 713.56 tons, or 38.88 per cent.
England, 30.56 tons, or 1.66 per cent.
Scotland, 20.00 tons, or 1.09 per cent.
Germany, 31.45 tons, or 1.72 per cent.
United States, 1,039.70 tons, or 56.65 per cent.
Totals, 1,835.27 tons, or 100.00 per cent.

Notes.—1. Shipped from New Liskeard to Scotland. 2. 410 lbs. shipped by express. 3. 1,000 lbs. shipped by express.

BRITISH COLUMBIA SHIPMENTS.

Following are the shipments for the past week, ended April 4th, and year to date:—

Boundary Shipments—

Mine.	Week.	Year.
Granby	24,687	271,433
Other mines	.....	462
Total	24,687	271,895

Rossland Shipments—

Centre Star	3,461	45,149
Le Roi	1,756	21,820
Le Roi 2	695	8,700
Iron Mask	38	38
Other mines	.....	462
Total	5,950	76,169

Slocan—Kootenay Shipments—

St. Eugene	419	7,091
Whitewater	46	358
Whitewater, milled	280	3,780
Poorman, milled	250	2,600
Queen, milled	185	2,395
Second Relief, milled	145	1,085
Richmond	28	468
Rambler-Cariboo	24	347
Nugget	24	306
Kootenay Belle, milled	25	175
Silver Cup	35	82
Mother Lode	15	15
Other Mines	..	13,332
Total	1,476	31,901

GRANBY SHIPMENTS.

For the purposes of comparison, the following table will show the output of the Granby mines for each month of the first quarter in 1907 and also in 1908, in tons:—

	1907	1908
January	34,192	74,203
February	32,465	80,155
March	63,826	110,223
Total	130,483	264,581

Granby shipments for week ended April 4th were 24,687 tons, against 27,288 tons the week previous. The total to date is 27,288 tons.

BRITISH COLUMBIA ORE SHIPMENTS.

Following are the shipments for the week ended March 28th and year to date:—

Boundary Shipments—

Mine.	Week.	Year.
Granby	27,288	246,746
Sally	23	67
Other mines	.....	395
Total	27,311	247,208

Rossland Shipments—

Centre Star	3,219	41,688
Le Roi	1,564	20,064
Le Roi No. 2	360	8,005
Evening Star	31	455
Other mines		7
Total	5,174	70,219

Slocan Kootenay Shipments:—

Total	1,879	30,425

The total shipments for the past week were 34,364 and for the year to date 347,852 tons.

BRITISH COLUMBIA SMELTER RECEIPTS.

Week Ended March 28.

Granby smelter receipts, Grand Forks, B.C., week, 27,288; year, 246,746.

Consolidated Company's receipts, Trail, B.C., week, 5,076; year, 66,026.

Le Roi smelter receipts, Northport, Wash, week, 1,564; year, 20,064.

Other mines, year, 1,390.

Total, week, 1,564; year, 21,454.

The total receipts at the various smelters for the past week were 33,928 tons and for the year to date 339,956 tons.

SOUTH AFRICAN JANUARY RETURNS.

Labor.—Gold Mines—Witwatersrand, 16,763 whites, 123,001 colored, 33,849 Chinese; other districts, 759 whites, 10,514 colored; total for Transvaal, 17,522 whites, 133,515 colored, 33,849 Chinese. Coal Mines—Total for Transvaal, 469 whites, 9,154 colored. Diamond Mines—Totals for Transvaal, 877 whites, 8,209 colored.

Coal Output.—Tota for Transvaal, 247,853 tons; value, £65,614.

Silver Output.—Total for Transvaal, 62,469 ounces; value, £7,305.

Gold Output.—Total for Transvaal, 561,166 ounces fine gold; value, £2,383,682.

Diamond Production.—The diamond production of the Transvaal, July-December, 1907, was as follows:—Number of mines contributing, 11; average number of diggers contributing, 27; total loads washed, 4,105,828*; carats of diamonds, 1,164,557; estimated value, £1,044,225.

*Includes 189,362 loads overburden.

Base Metals.—The base metal production for the month was as follows:—Copper ore, tons of 2,000 lbs., 42.5; estimated value, £1,360. Galena (lead), tons of 2,000 lbs., 461.8; estimated value, £3,487. Tin ore, tons of 2,000 lbs., 66.0; estimated value, £3,500. Flint, tons of 2,000 lbs., 82.0; estimated value, £732. Miscellaneous, tons, of 2,000 lbs., 32.2; estimated value, £966. Lime, tons of 2,000 lbs., 2,656.0; estimated value, £4,888.

Market Reports.

Coke.

April 8th.—Connellsville coke, f.o.b. ovens—

Furnace coke, prompt, $1.65 to $1.75.
Foundry coke, prompt, $2.15 to $2.25.

Pig Iron.

April 8th—Pittsburg—

No. 2 foundry, $16.15 to $16.65.
Bessemer, $17.50 to $17.90.
Basic, $16.15 to $16.40.
Malleable, $16.90 to $17.15.
Southern No. 2, $16.90 to $17.40.

Other Metals.

April 8th—New York—

Tin, Straits, 31.75 cents.
Copper, prime lake, 13 cents.
Lake, arsenical brands, 12.875 to 13 cents.
Electrolytic copper, 12.875 to 13 cents.
Sheet copper, 17 cents.
Copper wire, 14.5 cents.
Lead, 4 cents to 4.05 cents.
Spelter, 4.7 cents.
Sheet zinc, 7.5 cents.
Antimony, Cooksons, 8.75 cents.
Aluminium, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $23.50 to $26 per ounce.
Bismuth, $1.75 per lb.
Quicksilver, per 75 lb. flask, $45.

The reduction in the price of refined Cobalt in the United States from $2.50 per pound to $1.45, is of an extremely drastic character. Abroad the price has not suffered in the same way. The companies in the Cobalt camp, which have any quantity of cobalt, will doubtless find it advantageous to obtain quotations from the English interests. The tendency to sell direct to the London markets is likely to become more noticeable in the future with the undoubted growth of silver production in the camp.

Silver.—March 12th, 55 3-8; March 13th, 55 3-4; March 14th, 55 1-2; March 16th, 55 3-8; March 17th, 55 1-4; March 18th, 55 3-8; March 19, 55 1-2; March 20th, 55 3-8; March 21st, 55 1-4; March 23rd, 55 3-8; March 24th, 55 1-4; March 25th, 55 1-4; March 26th, 55 1-4; March 27th, 55 1-4; March 28th, 55 1-8; March 30th, 55 3-8; March 31st, 55 3-8; April 1st, 55 1-4.

Catalogue BX, issued by Wm. Ainsworth & Sons, Denver, Colorado, describes their precision engineering and surveying instruments. From their "Precision Factory" are sent out engineering instruments that are known to every mining engineer on the continent. This company's mining theodolites are especially worthy of notice. Amongst other types, their B Z type, with interchangeable auxiliary telescope, is worthy of notice.

Branches at COBALT and LATCHFORD, in the silver mining camp of New Ontario.

Easy to Lay

THE first ready roofings, made some thirty years ago, lasted a very short time.

Then manufacturers improved the goods and smooth surfaced roofings of various kinds were developed that would endure fairly well *if the top surface was given a coat of heavy waterproof paint every two years.*

Now comes Amatite—with a mineral surface which requires no painting and which will last longer *without painting* than the other kind did *with constant painting.*

The top surface, being mineral is unaffected by weather or climate.

It really protects.

The waterproofing material in Amatite is pitch—*the best resistant to water known.* Water will in time dissolve or disintegrate almost anything, but it is powerless against pitch.

Roofings of twice the price often do not protect as well because they are not waterproofed with pitch.

Amatite is easy to lay—any one can do the work. We furnish you free nails and liquid cement for laps.

Investigate the cost of Amatite in your locality. You will be astonished at its low price.

MINERALS
And How They Occur

A Book for Secondary Schools and Prospectors

BY

WILLET G. MILLER

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How They Occur" can be obtained from the Canadian Mining Journal

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

The Latest Book on the Electric Furnace

Electric Smelting is a subject of increasing importance to Canadian Engineers and this work contains a clear and connected account of the principle on which electric furnaces are constructed, the uses to which they can be put and the more important details of their construction. The articles upon which the book is based appeared in the Canadian Engineer during 1906.

The Electric Furnace

Its Evolution, Theory and Practice

By Alfred Stansfield, D. Sc., A.R.S.M.

Professor of Metallurgy, McGill University

208 Pages. Fully Illustrated. Price $2.00.

The evolution of the Electric Furnace from its simplest beginning is as briefly set forth as is consistent with clearness, together with the important facts relaring to its theory and practice.

The rapid growth of the Electric Furnace makes it increasingly difficult for the metallurgist to keep in touch with its recent developments. A few years ago it was a scientific curiosity, but now it threatens to rival the Bessemer converter, the open-hearth steel furnace, and even the blast furnace itself.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

ROYAL MAIL TRAINS
VIA
INTERCOLONIAL RAILWAY

CANADA'S FAMOUS TRAIN

The Maritime Express

Leaving Montreal 12.00 noon Fridays, carries the European Mail, and lands passengers, baggage, etc., at the steamer's side, Halifax, avoiding any extra transfer the following Saturday.

Special Trains

When inward mail steamers at Halifax do not connect with the regular train, the Maritime Express, westbound special train, with through sleeping and dining car attached, for passengers, baggage and mail, will leave Halifax for Quebec and Montreal, connecting with trains for Ottawa, Toronto and points west.

For further Particulars apply to

TORONTO HEAD OFFICE, 51 KING STREET EAST

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory **Open for Investment in the Province of Quebec**

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $1 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

The Canadian Miner's Buying Directory.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

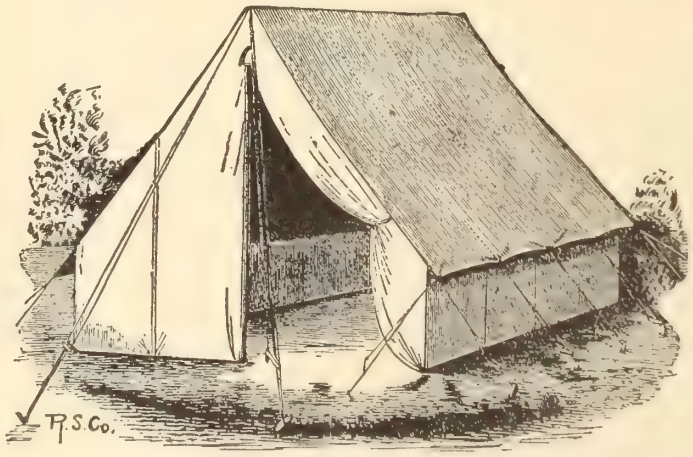
Deputy of the Minister of the Interior

N.B.—Unauthorized publication of this advertisement will not be paid for.

Men's Tweed Suits

Regular $10.50 Value for $7.95

M.J.104. After carefully going through the different makers' samples, to which our large buying powers give us access, we selected this material on account of its worthiness in wearing qualities and its neat yet handsome pattern, which lends itself particularly well to this style of suit. By contracting for the entire output of this line, we have secured a price concession which enables us to offer our customers this big saving on an honest suit.



The material is an imported English tweed of durable quality, in a dark ground with lighter intermixture, giving a pepper and salt effect; into this is woven red and blue stripes and cross stripes, forming a subdued broken check pattern, being neat and quiet—a material which any gentleman would select for business or general wear, made in a single-breasted sack style, lined with a fancy twilled mohair lining, stayed with linen, shoulders and front reinforced with shrunk linen duck and hair cloth, guaranteed to retain their shape, well tailored and perfect fitting, sizes 35 to 44. Regular $10.50 value,

Our Special Price 7.95

A Sensational Tent Offer

$16.00 Value for $11.95

M.J.105. Experienced summer campers prefer this style of tent because it is so easily erected, and is practically storm-proof. By placing large orders with one of the largest manufacturers on the continent we are able to offer the BIGGEST TENT BARGAIN you have ever heard of. This tent is made of full weight 8-oz. duck. The seams are double stitched and strain points reinforced. Height, 8 ft.; length, 12 ft; width, 9 ft. 6 in.; height of wall, 3 ft. Complete with poles, pegs and ropes. You will find that the lowest price for this tent elsewhere is $16. Our special price **$11.95**

Money Refunded if for Any Reason you are Not Satisfied

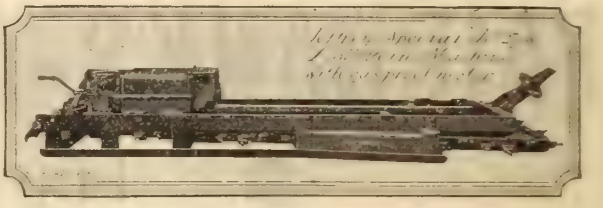
RAND AIR COMPRESSORS

EFFICIENT AND ECONOMICAL

Complicated mechanism in air compressor design is regarded as an element of weakness and it is the elimination of such non-essentials that has produced the up-to-date RAND Machine; a machine which operates with the minimum of attention and repairs.



Our Catalogs describe Rand Compressor Construction.

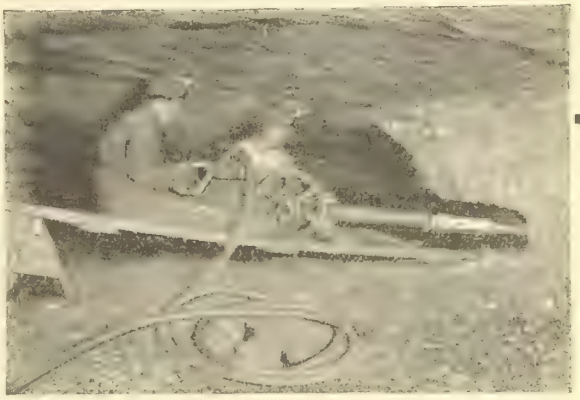
FOR THE
DEISTER CONCENTRATORS



The Coniagas Mines' and the Buffalo Mines' plants at Cobalt have been equipped with Deister tables and the results obtained are entirely satisfactory. The Deister No. 3 Slimer is especially a surprise in saving more silver than any Vanner heretofore tried.

C. B. FITCH, - Canadian Agent
FORT WAYNE, INDIANA

Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work by reason of their high air efficiency, substantial design, and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)

SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines, in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905.
Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 500,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

R. G. DRINNEN, Superintendent. G. G. S. LINDSEY, General Manager.

OFF FOR THE COAST

"See Canada First"

Go yourself this summer, see with your own eyes the wonderland of Western Canada. Wide sweeps of prairie, following the timber country, and followed by the finest mountain scenery in the world, ranges of peaks thousands of feet high, all can be

seen at ease from the trains of the

CANADIAN PACIFIC RAILWAY

No more delightful vacation trip imaginable. Not an expensive trip, summer tourist rates and occasional excursion rates considerably reduce the cost.

Let us help you plan your tour, so you will miss nothing. It will be a pleasure to answer enquiries.

The Murphy Drill

Our New Catalog

"THE CARNAHAN SYSTEM OF BREAKING ROCK"

with illustrations showing the hand drill, heavy capacity drills for deep mine work, also drills in operation in stopes and cross-cuts, and every part of mechanism necessary in the construction of a first-class air hammer. These drills are the outcome of over thirty years study and experience in practical mining by the most expert miners and mechanical engineers. The weaknesses so common to the ordinary rock drill, WE have succeeded in eliminating.

In hard rock one man can easily drill 45 feet a shift with a No. 1 drill, 65 feet with a No. 2, and 90 feet with a No. 3. He can put his holes to take advantage of the ground the same as if he were doing the work by hand. Does this not speak for itself? Fill out and mail this coupon to us today, and this valuable book, "Carnahan System of Breaking Rock," will be mailed to you without delay.

LAWSON AND THE YUKON.

Thomas W. Lawson has been sufficiently pilloried. Technical and financial journals on both sides of the Atlantic have taken pains to apprise their readers of the fact that Lawson is a false prophet.

Were investors in Lawson's stock of an enquiring turn of mind, they could easily find out that his promises are specious. Authorities agree that he is shifting onto the shoulders of the "gelatine-spined" public an investment that at best will pay an absurdly low rate of interest.

Some one has accused Mr. Lawson of being a clever advertiser. We would consider the person who could substantiate this accusation a genius of the first water.

An advertiser Mr. Lawson is—unscrupulous, unveracious, impudent. But not one element of cleverness is to be detected in his frothings.

We are tempted to believe that those who are deluded into "blowing" themselves on Mr. Lawson's Yukon gold, deserve what they will get.

However, our space is too valuable to devote to Mr. Lawson and his lucubrations. We wish only to announce that civil proceedings are soon to be instituted against his promotion for failure to comply with the requirements of the Ontario Companies' Act. THE CANADIAN MINING JOURNAL is laying the information.

ETHICAL.

A contemporary has alluded to the apparent similarity existing between the 'Miami Company" scheme and sound English flotations. There are two important respects in which this similarity does not hold.

In Great Britain the requirements of a rigid companies' act apply to all flotations and, to a large degree, safeguard the public. No such federal enactment exists in the United States.

In Great Britain, as on this continent, it is unusual for the consulting mining engineer to play the part of promoter. In this case Mr. J. Parke Channing, vice-president of the company, is also the consulting engineer whose report is quoted in the prospectus, and upon his representations the public are asked to invest.

We may justly infer that Mr. Channing, as vice-president, is directly interested in the financial success of the Miami Copper Company. Is this in accordance with that unwritten code of ethics to which mining engineers here and elsewhere conform? Is it wholesome from a business point of view? Is not the report of an independent mining engineer indispensable?

THE HAMSTEAD MINE FIRE.

All coal-mine operators will welcome Mr. F. W. Gray's article on the use of breathing apparatus at the Hamstead mine fire.

We are not overstating the case when we say that Mr. Gray deserves the warmest praise for the efficient and practical manner in which he is taking up the subject of rescue work.

The press reports of this disaster have been incomplete and misleading. Mr. Gray's clear analysis of the circumstance is therefore timely and welcome.

It will be seen that there is no just cause for dissatisfaction with the rescue apparatus used. Also, Mr. Gray makes it evident that it is of the utmost importance that each colliery should possess its own complement of respirators and should keep a thoroughly trained corps of selected men. Both men and apparatus must be ready for instant service.

There is inspiration in the heroism of Thorne, one of the Tankersley Station men, who made repeated descents into the mine in the vain hope of saving the lives of others. His example is all the more profitable when it is known that he had trained unremittingly and had become thoroughly accustomed to the use of the Draeger helmet.

SPANISH.

Many of the graduates of Canadian mining colleges have had cause to regret their ignorance of Spanish.

A prominent and successful mining engineer residing in Mexico, has recently suggested to us that Spanish should be made a compulsory subject in the course mapped out for mining students. Since our correspondent is himself a Canadian and a graduate of a Canadian college where Spanish is not included in the mining course, he speaks with knowledge and feeling.

In our own experience we have known of numerous instances where young mining engineers were unable to accept positions in Mexico and other Spanish-American countries, simply because of their ignorance of the langauge. In all other respects they were amply qualified.

The mining engineer is the truest cosmopolite. To him neither the pink tea nor any other social futility should appeal. His country is that in which his work lies. It may be Siberia or the Yukon or Peru. But Canadian mining engineers, if they do not find work in Canada, are much more likely to look for it (and find it) in Mexico than anywhere else. Our correspondent's suggestion is therefore in accordance with the dictates of common horse-sense.

A VALUABLE REPORT.

Mr. A. A. Cole, mining engineer to the Temiskaming and Northern Ontario Railway Commission, has compiled and published a report on the Cobalt district for the year 1907.

In addition to conveniently tabulated figures of production, much useful information concerning the various smelters is included. Canadian, United States and European smelting rates and schedules are given in full. The flow-sheets of five concentrating plants are reproduced graphically.

Altogether Mr. Cole's report is interesting and valuable.

It will require the passage of but very few years to increase vastly the difficulty of finding out certain facts about the early history of Cobalt. A clear record of conditions published now is worth reams of dubious speculations some time hence. Both from a thoroughly practical and from a sentimental point of view, it is well to write history while events are yet warm in the memory.

The mining public should be grateful to the Temiskaming and Northern Ontario Commission and to Mr. Cole.

OFFICIAL BULLETINS.

The British Columbia Bureau of Mines has commenced issuing official bulletins. It is no longer necessary to await the publication of the annual report to get information concerning new districts or important work in old districts. Bulletin No. 1, by Mr. W. Fleet Robertson, Provincial Mineralogist, describes the mineral locations on Moresby Island. Here, incidentally, is situated the Ikeda mine, owned and operated by the Japanese firm of Awaya, Ikeda and Company of Vancouver.

We wish to commend to the attention of the mining departments of other provinces, this departure from established routine. As we have pointed out many times, timely bulletins are infinitely to be preferred to the bulky and belated annual reports.

Editorial Notes.

News notes, photographs and enquiries from our readers are always welcomed. Our news columns could be greatly enhanced in value if readers would advise us from time to time of happenings in mining circles. Canada is a large country.

Mr. Courtenay De Kalb, well known in Ontario, has accepted the position of associate editor of the *Mining and Scientific Press* of San Francisco. For some years, Mr. De Kalb occupied the chair of mining and metallurgy at the School of Mining, Kingston. He was also Inspector of Mines for the province of Ontario.

Mr. De Kalb is a mining engineer of wide experience. He has contributed many articles to technical papers. As a writer he is incisive and polished. We congratulate our western contemporary upon this important addition to its staff.

LE ROI No. 2, LIMITED, ROSSLAND, B.C.

GEO. A. OHREN.

A mining company that has demonstrated in a satisfactory manner that Rossland gold-copper ores can be mined at a good profit is the Le Roi No. 2, Limited, which up to the time of this writing has paid $838,000 in dividends, on a capital of £600,000 divided into 120,000 shares of £5 each, since the present company took it over from the British American Corporation, who controlled its interests to 1898. This company has not mined on as large a scale as some of the other mines in Rossland camp but its affairs have been managed in an economical and business-like manner and the result has been substantial dividends for the shareholders, who have come to look upon it as a steady and confidence worthy mining enterprise.

The group comprises the Annie, Annie Fr., Josie, No. 1, No. 1 Fr., Thekla, You Know, Rockingham, Surprise, Poorman, Golden Dawn, and Copper Queen mining claims in Rossland camp. The principal mining operations are carried on through the Josie property on which the Josie shaft, 900 feet in depth, is situated. The product of the mine is hoisted through the Josie shaft with a 150 horse power electrical hoisting engine, a duplicate of which engine they have in the shaft house on the No. 1 claim. The shaft on the No. 1 is 650 feet in depth and some of the best copper ore in the camp has been taken from the No. 1 workings. Commodious ore bins, blacksmith and machine shops, framing shop, superintendent's residence and other mine buildings are located on the Josie claim. The concentrator is situated across a small gulch from the Josie workings. The air drills used are of the 2 1-2 inch, 3 1-2 inch and 3 5-8 inch sizes. Those with the 3 5-8 inch cylinders are used for the heavy work, such as sinking, etc., while the smaller machines are used for stoping.

The mine is at present producing about 2800 tons of "first-class" ore per month, which is treated at the Trail smelter. Approximately 1,100 tons of "second-class" ore is treated each month at the concentrator. Ore from this mine occurs in much narrower veins than in the Centre Star or Le Roi but is of a very much higher grade, as will be seen by the following figures:

The "first-class" ore mined during the year ended June 30th., 1907, amounted to 18,000 tons. This ore carried:

Gold,	.707 ounces at $20.	$14.140
Silver,	.751 ounces at $0.6769c....	5.508
Copper,	1.512 per cent at $0.2188c....	6.614
	Gross value of ore per ton	$21.262

LE ROI NO. 2 AND LE ROI MINES, ROSSLAND, B.C.

The smelting charges were $6.12 per ton.

Of "second-class" ore 11,840 tons were put through the mill, which carried per ton:

Gold	.84 ounces
Silver	.144 ounces
Copper	.396 ounces

and 706 tons of concentrates were shipped which assayed as follows:

Gold	.933 ounces
Silver	.859 ounces
Copper	1.22 per cent

The output shown above, with 3,400 tons of ore left broken in the stopes, gives a total production for the year of 33,069 tons.

The cost of mining the ore is made up as follows:

Ore production	$1.95
Ore sorting	.25
General expenses	.49
Power plant	.74
Mine general	.97
Diamond drilling	.48
	$4.88
Depreciation	1.92
Total cost per dry ton mined	$6.80

The shipping ore is carried by tramway from the Josie ore bins to bins at the railway siding where it is loaded for shipment to the smelter. The "second-class" ore is conveyed by tramway to the concentrator, where it is crushed in jaw crushers and then goes into Trent Chilian mills. From the mills it is run on to four Wilfley tables arranged in two sets, the headings running over the first two tables and the product from these tables being treated on the other two. The tailings from the second tables are not treated. During the year under review it is estimated that they carried the following values:

	Cents.
Gold	.030
Silver	.098
Copper	.344

Electric power for operating the concentrating and hoisting plants is secured from the lines of the West Kootenay Power & Light Company and costs approximately $40 per horse power per annum. Compressed air for operating the mining machinery, smoke blowing, etc., is derived from the Consolidated Company's compressing plant and costs Le Roi about $20,000 per annum. Nearly forty per cent of this cost of air power is for air that is used in smoke blowing and ventilation.

Some of the costs of development work, etc., are:

Drifting and crosscutting per foot	$14.576
Stoping	4.88
Diamond drilling	2.61

The company has an option on and is working the Vancouver Group (silver-lead) near Silverton, B. C. This group consists of the Vancouver, Vancouver Fr., Zilor, Silver Star, Kelley, Napia, Ricardo, Prior and Mountain Boomer, comprising 527 acres. They are now treating about 2,400 tons per month from this property. There is no trouble separating the zinc from the lead with this ore. The zinc concentrates are sent to Antwerp under contract. The cost of milling is about 40 cents per ton. The work here is being done by hand and costs:

Drifting and crosscutting per foot	$13.24
Sinking	21.24
Raising	9.61

They shipped 21,079 tons of this ore, which assays:

Silver	13.6 ounces
Lead	3.7 per cent
Zinc	4.7 per cent

and produced 1,100 tons of lead concentrates assaying:

Silver	117.2 ounces
Lead	60. per cent
Zinc	11.3 per cent

The 1,316 tons of zinc concentrates carried:

Silver	40.4
Lead	2.3
Zinc	45.2

LE ROI No. 2 CONCENTRATOR ROSSLAND, B.C.

A quantity of picked lead ore was also shipped and the output was worth in all $119,030.

The Le Roi No. 2 holds, roughly, a one-third interest in the Conclurry Syndicate, on which they have recently received a dividend of $21,506, which is a valuable asset.

The balance in favor of profit and loss for the year was $61,897 and the balance of cash on hand at Rossland and London amounted to $22,500.

In conclusion, the Le Roi No. 2, Limited, has certainly proved that with economy and careful management the ore bodies in this district can be worked at a profit and there is no doubt that the mine will go on paying dividends to the shareholders for many years to come.

THE USE OF OXYGEN BREATHING APPARATUS AT THE HAMSTEAD MINE FIRE.

By F. W. Gray.

The English newspapers of the 6th of March record a most gallant attempt at the rescue of 21 entombed miners by trained men equipped with oxygen breathing apparatus, which was unfortunately unsuccessful.

A fire broke out in the Hamstead Mine, which is situated at Perry Barr near the city of Birmingham, on Wednesday night the 4th of March. Thirty men went down on the night shift, but of these nine managed to make their way through the smoke and fumes and escaped by way of the upcast shaft. The other twenty-one had however gone into the far workings and were cut off by the fire, which originated near the bottom of the downcast shaft. Under the direction of H. M. Inspectors rescue operations were carried on throughout the night and Thursday morning, but without avail. Telegrams were sent for the Normanton and Tankersley Rescue Corps. The Normanton men have been trained at Mr. W. E. Garforth's station at Altofts Colliery in West Yorkshire. They wear the Weg apparatus, Mr. Garforth's invention. The Tankersley Station is situated near Barnsley,South Yorkshire, and the apparatus worn by the party despatched to Hamstead was the Draeger. Full descriptions of both these stations will be found in the Transactions of the Institute of Mining Engineers. A friendly rivalry has existed between the men of these two stations for some time past, and to the call now sent they responded with the utmost promptitude. Mr. Garforth himself led the Normanton party of five men, Hopwood, Haslop, Cranswick, Whittingham and Welsby. The Tankersley party were at work in their own mines when the summons came. They were Thorne, Taylor and Outram, accompanied by A. T. Winborn the Superintendent of the Tankersley Station.

The parties arrived early in the afternoon of Thursday and proceeded at once to make preparations for descending the mine by getting acquainted with the plans. Previous to their arrival attempts had been made to penetrate the workings by rescuers unprovided with the apparatus, but they could not descent the shft. It was thought that the fire could not have reached the entombed men, who were in all probability in safety in the remoter workings, and strong hopes were entertained of the possibility of their rescue. At 3-22 p.m. three of the Normanton men made the first descent down the upcast shaft, and remained below over an hour. They returned however without having been able to find any sign of life, except a partly asphyxiated cat. The second attempt was made by two of the trained men and the manager of the mine at five o'clock. They came up at ten minutes after six, not having been able to find anyone. The third party went down at 7.30, having arranged to return not later than 9 o'clock. At 8.30 two of them came up, Thorne and Outram. Outram was overcome by the heat, but Thorne obtained fresh oxygen cylinders and again went below. He returned about nine o'clock with Whittingham, both men in a state of exhaustion. When they recovered they explained that Whitting and Welsby had penetrated some 800 yards into the mine, when Welsby was overcome by the heat and the stooping. Whittingham dragged him as far as possible, but had to leave Welsby owing to the drain on his own resources. Making his way to the shaft, he met Thorne, who had to assist him. Thorne showed most remarkable endurance, having made three distinct descents. Two other men from the Normanton party then descended to rescue Welsby, if possible, but returned without finding him. Further operations had to be postponed, as the rescuers were all exhausted, and their oxygen supply was running short. Next morning they attempted another descent, but after being twenty minutes in the shaft had to rap to be drawn up again. The shaft bottom was on fire and the heat was unendurable. Further particulars are not to hand, but we understand the twenty-one men entombed and Welsby were finally abandoned.

At the first reading it would appear as if the first use of oxygen breathing apparatus in actual rescue work in England had resulted in na practical good and had also caused the death of one man more than the number involved in the original disaster, and this being the first time these devices have been brought prominently before the public eye, it is particularly necessary that a too hasty judgment should be avoided as to the merits of oxygen breathing apparatus.

There are several points to be considered: In the first place the fire broke out on Wednesday night, and the first party of rescuers did not arrive until 3 o'clock in the following afternoon. These men were 120 miles from their main station, only a bare dozen in number, and quite strange to the Hamstead workings, which is a difficulty that all miners will appreciate. They made a magnificent effort and faced death as a matter of course. They proved once more the depths of heroism that lie latent in the miner's nature when he goes to the help of his fellows in danger. But the task set before a dozen men was too great: to penetrate an unknown and burning mine with roads only four feet high in an unbreathable smoke at a temperature over 120 degrees was an awful tax on human endurance. Had the rescuers arrived earlier they might have succeeded in their efforts. But the fact that under such circumstances men were able to penetrate 800 yards and return, to visit the stables and locate the seat of the fire, proves the capabilities of properly trained men equipped with these devices.

Several points appear to be clear from the meagre reports now at hand:

1. To be really effective and useful in time of need, oxygen apparatus should be kept on the spot, and should be available for use instantly. Had the Normanton and Tankersley corps arrived at Hamstead before the heat of the mine became so great there can be no doubt that the doomed men would have been rescued, for smoke and fumes are no hindrance to the trained men who wear these apparatus.

2. It is absolutely necessary that men be trained in the use of these apparatus in conditions that are as nearly as possible actual conditions; that is, in really unbreathable gases, and with heavy work to perform. So far as can be learned the collapse of Welsby was not due to any fault in his apparatus, but to his physical failure under the trying conditions. The unfit can only be discovered by such methods. Men who undertake this work need good lungs and a sound heart, and should be of spare

and wiry build, preferably of medium height. Thorne, the man who made three descents and showed extraordinary heroism and endurance, was a man who had trained most conscientiously, having made several weight lifting records in smoke at contests between apparatus teams. A little previously he had undergone a similar experience in extinguishing a fire at Wharncliffe, Silkstone colilery (see Journal, Vol. I., p. 523). Untrained men are worse than useless when the emergency comes. No man knows his hidden indiosyncrasy until he makes the test.

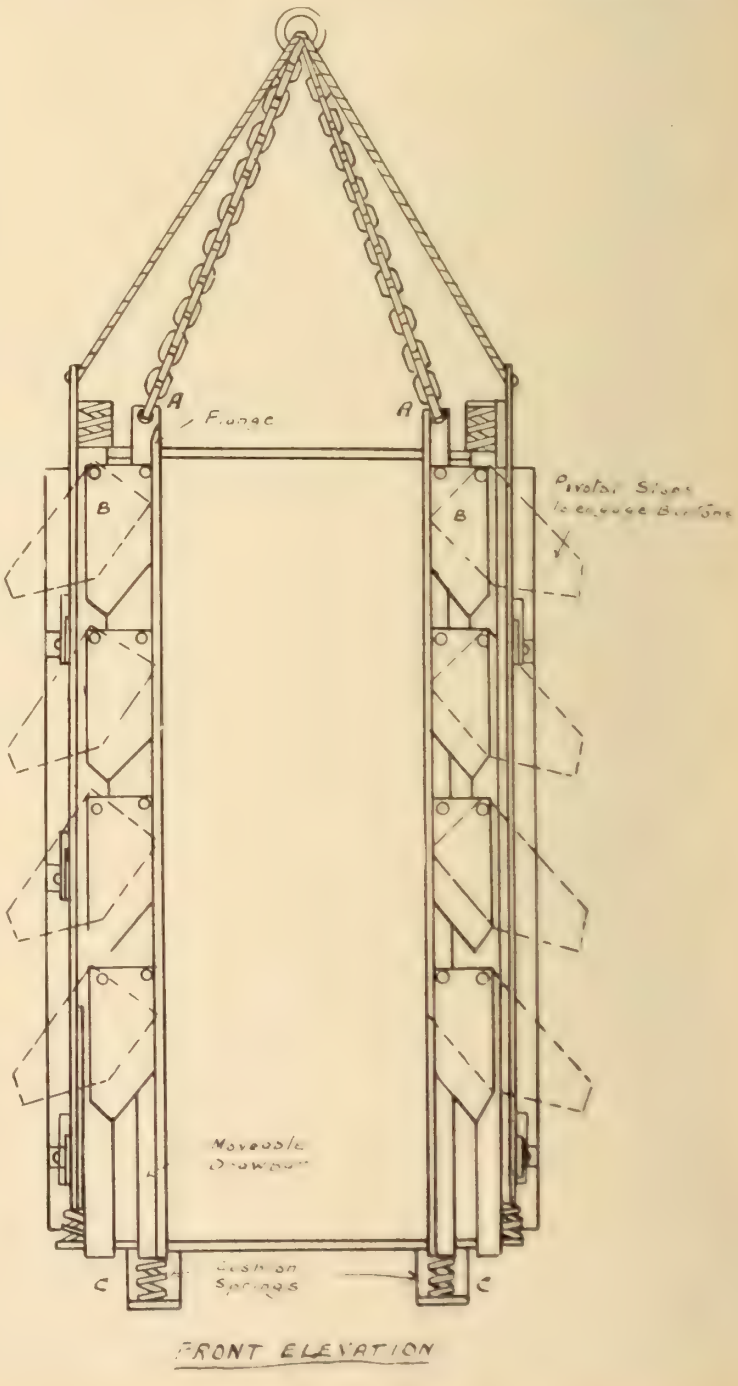
3. No party should consist of less than five men, and no man should be called upon to descend more than once in the day, otherwise his physical powers are liable to be too severely taxed. Relays of fresh men should be ready to take up the work.

4. An adequate supply of oxygen and cartridges should be at hand. Rescue parties need oxygen trunks to revive men whom they find unconscious and enable them to be carried through noxious gases to the open.

To be brief, the appropriation for rescue stations and their upkeep should be ample and sufficient. At a recent explosion in Germany eighty rescuers were present, all equipped with apparatus, etc. The number of sets of apparatus should be more than adequate, and the oxygen reserves never allowed to get below the safe point. Numerous and frequent drills are necessary, and it is foolish to exercise economy in renewals and supplies for practice. Further, the apparatus must be kept in constant use if it is to be in order when the call comes. Rescue corps differ in no wise from fire brigades in this particular. Constant practice is a prime necessity for both apparatus and men. As an example, the Tankersley station had four Draeger apparatus until lately, when forty would have been nearer its requirements. At least five apparatus for each mine served by a rescue station is the minimum that should be provided.

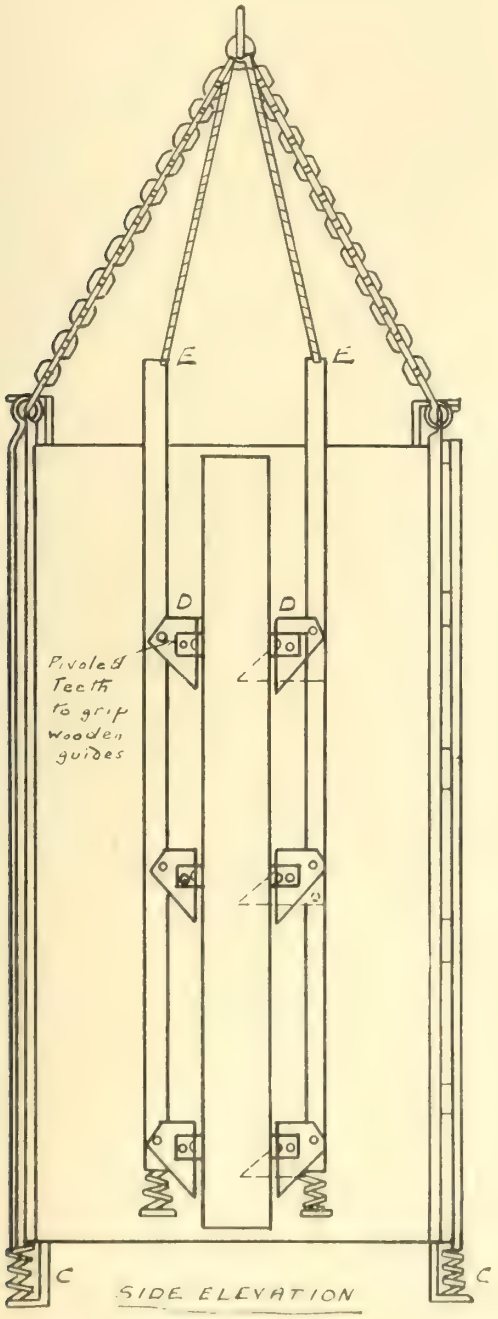
Up to very recently the English mines have been very poorly provided with breathing apparatus, the Normanton and Tankersley stations being the only ones. At present, however, large stations are in course of erection at Wath, South Yorkshire; in Lancashire and South Wales. Several are also to be found in Scotland, particularly that of the Fife Coal Company at Cowdenbeath.

The present experience, we think, while proving the capabilities of these apparatus, shows also the folly of half measures in the matter. If a job is worth doing at all it is worth doing well, and the provision of breathing apparatus, if contemplated at all by any mining company, should be contemplated in no niggardly way.



The fact that men were to be found willing to descend a strange mine, as they did at Hamstead, and trust their lives to their apparatus, shows the entire confidence they placed in its trustworthiness, and such men should not be called upon to suffer by reason of the lack of sufficient apparatus and trained rescuers. That under such conditions as prevailed in the Hamstead mine one of the volunteers succumbed is no reason for the non-provision of breathing apparatus. On the contrary, it is a reason for a more generous provision, and more extensive drill and practice work.

Another matter that strikes us very forcibly is that one mine or one company should not sponge upon another, or rest content in the knowledge that a neighboring company have men and apparatus if anything should happen in their own collieries that would make the use of breathing apparatus desirable. We know that willing volunteers will never be wanting when other men's lives are in danger, and it is hard to refuse aid under such circumstances. But what right has anybody to expect volunteers from another district to risk their lives in the unknown workings of a strange colliery at long distances from their base of supplies. Such men are like the mariner in uncharted seas, and they could be accused neither of cowardice nor inhumanity if under such circumstances they refused to endanger their lives. But we know they would not refuse, and therefore the national character of the matter becomes at once apparent.



A NEW SAFETY DEVICE FOR HOISTING CAGES.

(Communicated by our Glace Bay Correspondent.)

The recent deplorable accident at Sydney Mines No.1 Shaft caused by the failure of a safety catch, whereby two valued officials lost their lives, has drawn attention

here to safety devices for the prevention of accidents due to the detachment of mine cages from their supports. A Royal Commission has just finished its work in South Africa in investigating various safety devices for use in hoisting shafts of great depths. There are many patented safety devices for arresting mine cages in case of accidental descent which are applicable to circular walled hoisting shafts fitted with wire rope guides, or the ordinary woden or iron conductors, but none of these patents would be of much use in the rectangular timbered shafts

that are the rule on this continent. A device has however been recently patented by Mark Rideout, a young Glace Bay bricklayer, which is particularly adapted for local shafts. The following sketches will illustrate the working of the device.

The cage is suspended from the shackles by moveable flanged drawbars A at each corner, attached to which are a series of pivotal stops B held in vertical position retracted against the flange of the drawbar A, so long as the hoisting rope is taut. Whenever the tension of the rope is relaxed sufficiently the weight of the drawbar A, assisted by the springs C, causes it to fall, which projects the stops B outwards, so that they engage over the buntons of the shaft lining, thereby arresting the downward progress of the cage. The springs C serve also to absorb the shock of the suddenly arrested cage. At the same time the moveable drawbars E are drawn downwards causing the triangular teeth D to bite into the wooden guides. The action of the device appears very positive, and should be applicable to hoists of all kinds.

MOISTURE IN COAL.

The determination of moisture in a sample of coal is apparently simple and a result is easily obtained. The proper relation that this result bears to the original sample is, however, not so easily determined. Variations in this relation directly affect the application of all analytical work done upon the sample and the possibility of unaccounted-for moisture losses during the taking, shipping and preparing of the sample for chemical analysis too often receives little or no attention.

Care in Preparation and Shipment of Sample.—As a rule precautions to prevent moisture losses during the taking of the sample are not given sufficient attention and the too common practice of shipping the coarse sample by mail or express in canvas bags cannot be too strongly condemned where the moisture result is expected to represent the moisture in the coal as sampled. A sample of coal in a canvas or muslin sack may and usually does lose a large proportion of its loosely held moisture while in transit in warm mail or express cars, and the moisture results on such a sample can be only the moisture present in that particular sample in a more or less nearly air-dry condition. This is a point which has been too much overlooked in the past, and as a consequence many hundreds of published analyses of coal supposedly representative of the coal as mined really lack as much as several per cent. of the moisture actually present in the sample as mined or shipped.

Failure to guard against moisture losses is not necessarily of serious consequence on samples which have been selected more or less at random and sent to the chemical laboratory for analysis. On such samples the sender understands that the particular results obtained can represent the seam of coal only in a general way. The moisture result on these samples, while low and to that extent misleading, is a minor determination, as the ash and sulphur are usually the determinations particularly desired. When samples from actual steaming tests are handled in this way the unaccounted-for moisture losses will, of course, directly affect the accuracy of the test and the heat balance in such a case is necessarily misleading, as the coal usually analyzes better than the coal as actually fired under the boilers. This makes the unaccounted-for losses larger by perhaps several per cent. then they should be and some coals with an originally high moisture content and and consequent high moisture loss may be made to appear superior to really better coals with an originally low moisture content and a consequent lower moisture loss in transit to the laboratory. If correct moisture results are desired, the only safe way is to have the sample shipped from the mine or testing plant in air-tight cans, as was recommended by the committee.—E. E. Comermeier, in Mines and Minerals for April.

REPORT ON COBALT DISTRICT FOR YEAR 1907.

By ARTHUR A. COLE.*

The first seven pages of Mr. Cole's report to the Commission is taken up with statistics of ore shipments, most of which have appeared in different forms in previous issues of THE CANADIAN MINING JOURNAL. In the report, however, Mr. Cole has arranged the output of each mine by months for 1907 and by year for 1904 and 1907, inclusive.

On page 8 begins a list of smelter purchase schedules, etc., which is well worth reprinting.

One preliminary note, however, must not be omitted. Mr. Cole, alluding to the much more rapid increase of the tonnage than of the total value, explains that this indicates not that less rich ore is being encountered, but rather that a larger proportion of low grade ore is being shipped.

DISTRIBUTION OF OUTPUT.

The output for 1907 was distributed for treatment as follows:—

	Tons,	per cent.
Canada	2,585.05	17.40
England	167.34	1.13
United States	12,098.95	81.47
Totals	14,851.34	100.00

CANADA.

The Orford Copper Company.

The Orford Copper Company's smelter at Copper Cliff took almost all the ore that was shipped to Canadian smelters. At the end of the year the following was the purchase schedule and terms of settlement of the Orford Copper Company for silver and cobalt in arsenical silver-cobalt ores:—

Purchaser to make payment for—

94 per cent. of silver per ton of ore (2,000 lbs.) when same assays 4,000 ozs. and over.
93 per cent. of silver per ton of ore (2,000 lbs.) when same assays 1,200 ozs. and over.
92 per cent. of silver per ton of ore (2,00 lbs.) when same assays 800 ozs. and over.
90 per cent. of silver per ton of ore (2,000 lbs.) when same assays 500 ozs. and over.
85 per cent. of silver per ton of ore (2,000 lbs.) when same assays 300 ozs. and over.
80 per cent. of silver per ton of ore (2,000 lbs.) when same assays 150 ozs. and over.

Purchaser to make payment of—

$30 per ton of ore (2,000 lbs.) when same contains 12 per cent. cobalt and over.
$20 per ton of ore (2,000 lbs.) when same contains 8 per cent. cobalt and over.
$10 per ton of ore (2,000 lbs.) when same contains 6 per cent. cobalt and over.

No payment will be made for cobalt in ores containing less than 6 per cent. cobalt, nor in which the nickel contents are higher than the cobalt contents.

Further, the right is reserved to return, at shipper's expense, any such ores (i.e., nickel contents higher than cobalt contents) received at Copper Cliff.

Ore is to be delivered by seller to the Canadian Copper Company, f.o.b. cars, Copper Cliff, Ont., ore to be at shipper's risk until sampling is undertaken, as purchaser can assume no responsibility for the same until the ore has been taken into its sampler.

Purchaser to sample at its expense, purchaser's and seller's representatives to be present. Assays to be made at Ledoux & Company, of New York, at seller's expense, which assays are to govern in settlement.

Payment for 50 per cent. of the silver returnable to the seller, as per the above scale, to be made at the New York official price for silver on the first settlement date, which shall be 45 days after the date on which sampling of the ore is completed, the remaining 50 per cent. to be paid 45 days later. The purchaser, however, reserves the right to deliver on either or both of the settlement dates above specified, in lieu of cash, at its option, such silver bullion (commercial bar silver) as is due the seller in settlement upon these dates. Such delivery to be made in New York City.

Payment for cobalt will be made as per the above scale when the cobalt content of the ore comes within the specifications mentioned, settlement to be made 50 per cent. on each of the two due dates for silver, namely, 50 per cent. in 45 days and 50 per cent. in 90 days after the completion of sampling the ore.

Purchaser does not guarantee date when ore will be sampled, but undertakes to complete same promptly after the ore reaches its turn for sampling.

The freight rate on ore from Cobalt to Copper Cliff is $5.20 per ton.

The Deloro Smelting and Reduction Company.

The Deloro Smelting & Reduction Company, with works at Deloro, Ontario, is just starting operations on Cobalt ores and is offering the following prices for them:

Deloro Schedule.

Silver.—Ore containing 100 to 200 ozs. per ton pay 85 per cent.; ore contain 200 to 500 ozs. per ton pay 90 per cent.; ore containing 500 to 800 ozs. per ton pay 91 per cent.; ore containing 800 to 1,000 ozs. per ton pay 93 per cent.; ore containing 1,000 to 2,000 ozs. per ton pay 94 per cent.; ore containing 2,000 ozs. and over per ton pay 95 per cent.

At New York quotations 30 days after agreement of assays.

Arsenic.—Ore containing not less than 10 per cent arsenic pay for all arsenic contained:

10 per cent. to 30 per cent—1 cent per pound arsenic.
30 per cent. and over—1 1-2 cents per pound arsenic.

Cobalt.—Ore containing not less than 6 per cent. cobalt—

6 per cent. to 10 per cent. cobalt pay $10 per ton ore.
10 per cent. and over cobalt pay $20 per ton ore.

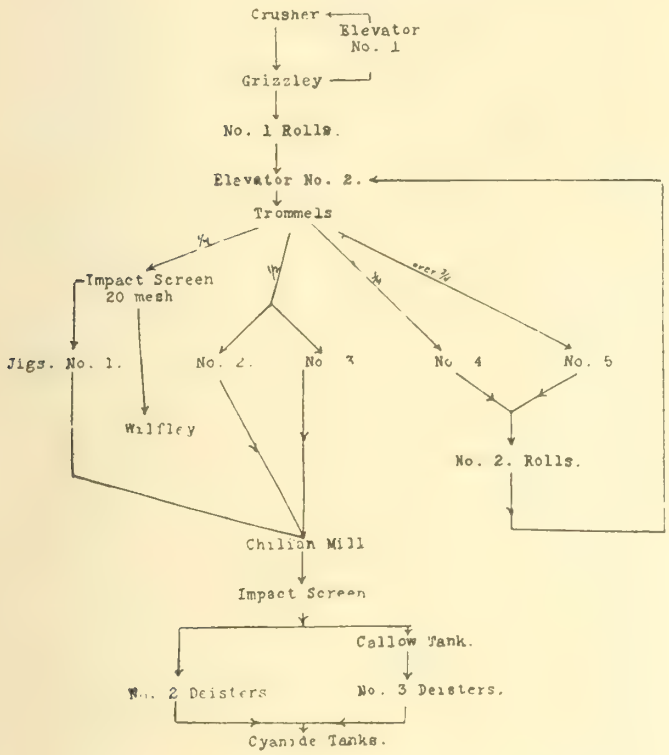
Treatment charges in all cases $10 per ton (2,000 lbs.) ore.

No charge for sampling.

No penalties for "insoluble matter."

Ore to be delivered in carload lots, f.o.b. Marmora station, Central Ontario Railway.

*Mining Engineer, Temiskaming & Northern Ontario Railway Commission.



This tariff is subject to change without notice.

The freight rates on ore from Cobalt to Marmora station is $7 per ton.

ENGLAND.

The Anglo-French Nickel Company of Swansea, Wales, was the only European company that bought ores from the Cobalt camp.

(1) BUFFALO CONCENTRATOR.

This company wished ores solely for their cobalt contents, and paid nothing for the silver.

The following is the schedule of average prices paid for Cobalt ores during 1907, by the Anglo-French Nickel Company, but before the end of the year these prices were cancelled:—

8 to 10 per cent. cobalt, 30 cents per pound for metallic cobalt.
10.1 to 12 per cent. cobalt, 35 cents per pound for metallic cobalt.
12.1 to 14 per cent. cobalt, 40 cents per pound for metallic cobalt.
14.1 to 16 per cent. cobalt, 45 cents per pound for metallic cobalt.
16 per cent. cobalt and over, 50 cents per pound for metallic cobalt.

The freight rate on ore from Cobalt to Swansea, Wales, is $13.98 per ton.

UNITED STATES.

American Smelting and Refining Company.

Eighty per cent. of the camp's output went to the United States and most of this was taken by the American Smelting & Refining Company at their works at Perth Amboy, N.J.

The following is the schedule of prices offered by this company at the end of the year for silvercobalt ores:—

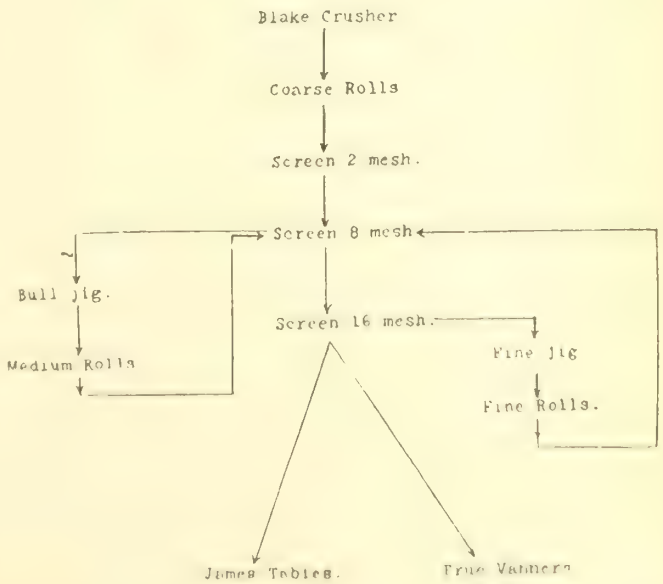
American Smelting & Refining Company's schedule for ores assaying under 1,500 ozs. per ton—

Silver.—Pay for ninety-three per cent. of the silver contents at the New York quotations as given by Messrs. Handy and Harman to Western Union Telegraph Company, on the thirtieth day after agreement of assays.

Working Charge.—Nine dollars per ton of two thousand pounds dry weight, plus one-half cent per ton of each ounce of silver contained.

Arsenic.—Should arsenic be contained in excess of five per cent., an addition to the working charge will be made at the rate of twenty-five cents per dry ton for each per cent. of arsenic in excess of five per cent.

Insoluble Matter.—An addition to the working charge will be made at the rate of seven cents per dry ton for each per cent. of insoluble matter contained in excess of iron.



Payments of net proceeds of shipments will be made on the thirtieth day after date of agreement of assays.

Ores assaying 1,500 ounces per ton or over—

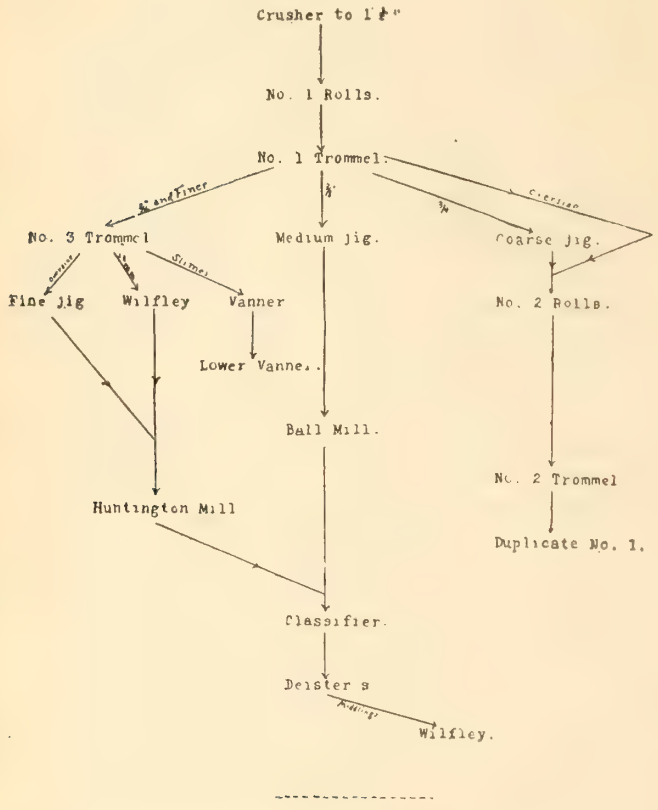
These ores will be treated at the Perth Amboy plant by the cupelling process, separately from any other ores, in the presence of the shipper's representative, making payment immediately on production, for all of the silver recovered in silver bars at the New York quotation prevailing on date of production of bars, as given by Messrs. Handy & Harman to Western Union Telegraph Company.

All by-products recovered during the process, such as slags, test bottoms, etc., will be sampled in the presence of the seller's representative, and ninety-eight per cent. of the silver contents of same will be paid for on the basis of assays arrived at by averaging the smelter's results with those of the seller's representative, providing the differences are not unusual; payment being made on the thirtieth day after date of agreement of assay and

(2) COBALT CENTRAL CONCENTRATOR.

at the quotation prevailing on that date; any unusual differences in assays to be adjusted by umpiring in the usual manner.

Working Charge.—$125 per ton of 2,000 pounds of ore dry weight plus one per cent. per ounce of silver paid for.



On ores running under 1,500 and above 400 ounces per ton the shipper is advised to consign through Messrs. Ledoux & Company's works at Bergen Junction, with privilege of sampling in transit. At any sampling or other operations at Perth Amboy plant the seller is entitled to have a representative present.

The freight rate on ore from Cobalt to Perth Amboy, N.J., is $10.20 per ton.

Some of the comparatively low grade ores proved suitable for mixing with certain western ores, and for this reason towards the end of the year a considerable tonnage of these ores was shipped to the American Smelting & Refining Company's works at Denver, Colorado. A reduction was made in the smelting charge to offset the increase in freight rates.

The following companies were also occasional buyers of silver-cobalt ores during the year:—

(3) Coniagas Concentrator.

Balbach Smelting & Refining Company, works at Newark, N.J.

United States Smelting, Refining & Mining Company, Chrome, N.J.

Pennsylvania Smelting Company, Carnegie, Pa.

Progress During the Year 1907.

Not only have the old shippers increased their shipments during the year, but the number of shipping mines has been increased by ten, making a total of twenty-nine, and notwithstanding the fact that some of these only shipped small quantities, the increase is noteworthy. It is all the more satisfactory when it is remembered that the shipments for several months were curtailed on account of labor troubles and also that they increased towards the end of the year in the face of a falling price of silver.

The average monthly price of silver in refined ounces in New York is given in the following table, taken from the Engineering and Mining Journal:—

Month.	Average Price.
January	68.673
February	68.835
March	67.519
April	65.462
May	65.981
June	67.090
July	68.144
August	68.745
September	67.792
October	62.435
November	58.677
December	54.565

The average price for the year 1907 was 65.327, the highest price being 70.125 cents on January 3rd, and the lowest 52.5 cents on December 21st.

Most of the mines now have machinery installed and development work can be pushed with greater rapidity. The following table is a fair index of the advance in this line:—

Horse-power boiler capacity of the Cobalt camp at end of

Year.	H.P.
1904	Zero
1905	150
1906	3,406
1907	7,918

The mines of the district now have 74 steam plants and two gas producer plants, and in connection with these are 51 compressor plants, as compared with 20 at the end of 1906.

A favorable result of the installation of this machinery is that more development than formerly is being done per ton of ore shipped, and there is to-day more ore blocked out than there was a year ago.

Concentration.

From the very opening of the Cobalt district it was realized that the problem of treating the low grade ores would form a very important feature in its industrial future. Nearly every mining school and testing laboratory on the continent has run small mill tests on the ore, and from the information thus gathered mills have been designed. There are six mills in the camp, four mine mills being in active operation, and two custom mills nearing completion.

They belong to the following companies:—

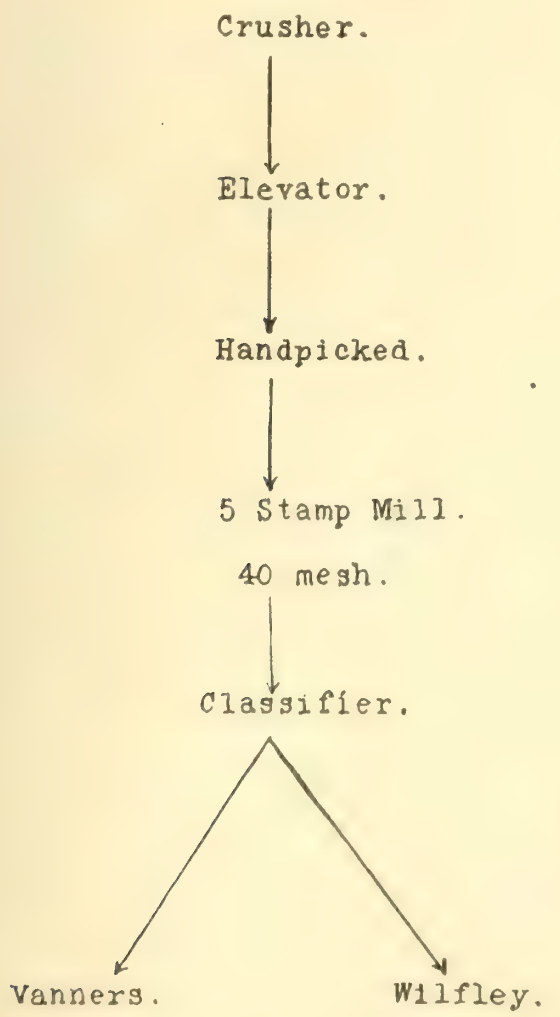
Mine Concentrators—

(1) The Buffalo Mines Company, Limited.
(2) Standard Cobalt Mines, Limited (Cobalt Central).
(3) Coniagas Mining Company.
(4) McKinley-Daragh-Savage Mines of Cobalt, Limited.

Custom Concentrators—

(5) Muggley Concentrators, Limited.
(6) Cobalt Concentrators, Limited.

All use water concentration with the exception of the Cobalt Concentrators, Limited, which is installing a penumatic process plant.



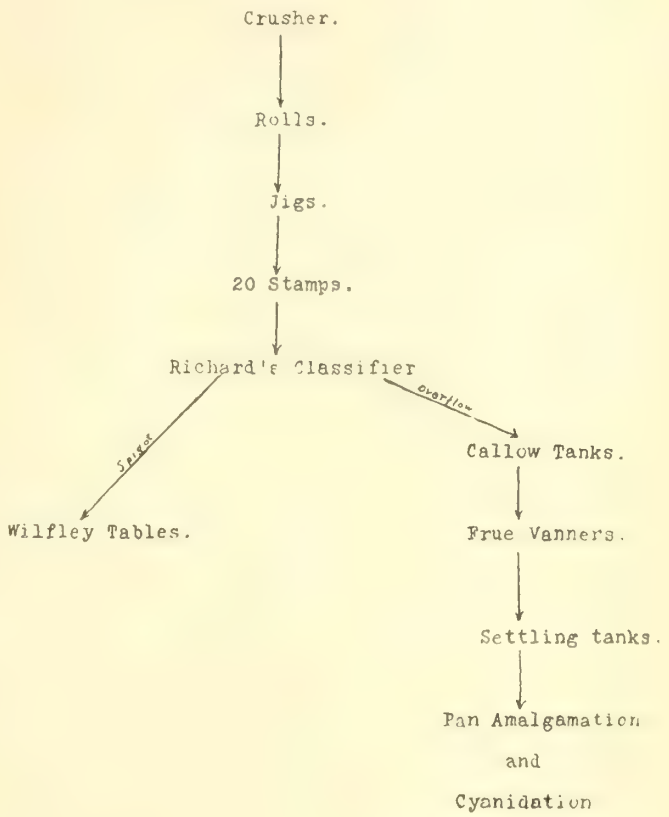
The following flow sheets illustrate in outline the general methods of concentration adopted.

(5) MUGGLEY CONCENTRATORS, LIMITED.

This company has a mill almost ready to start operations and is contracting for ore on a tariff of which the following is an outline:—

On ore yielding 20 to 60 ounces silver per ton, crushed, pay 50 per cent. net silver value.
On ore yielding 60 to 80 ounces silver, per ton, crushed, pay 55 per cent. net silver value.
On ore yielding 80 to 100 ounces silver per ton, crushed, pay 60 per cent. net silver value.
On ore yielding 100 to 125 ounces silver per ton, crushed, pay 65 per cent. net silver value.
On ore yielding 125 to 150 ounces silver per ton, crushed, pay 70 per cent. net silver value.
On ore yielding 150 to 175 ounces silver per ton, crushed, pay 75 per cent. net silver value.

(4) MCKINLEY-DARRAGH CONCENTRATOR.



On ore yielding 175 ounces silver and up per ton, crushed, pay 80 per cent. net silver value.

By net silver value is meant the gross silver value less smelting charges.

LEASES.

During 1907 the following mining companies operated on a royalty basis on mineral lands owned and leased by

(5) MUGGLEY CONCENTRATOR.

the Temiskaming & Northern Ontario Railway Commission:—

(1) City of Cobalt Mining Company.
(2) Cobalt Townsite Mining Company.
(3) Nancy Helen Mines, Limited.
(4) Railway Reserve Mines, Limited.
(5) Right of Way Mining Company.
(6) Wright Mining Company.
(7) Jack Pot Silver Mining Company, Limited.

The report is concluded with detailed statements of the equipments and mining operations of the seven companies mentioned above.

In his introductory paragraphs Mr. Cole makes allusion to the rapid and regular growth of mining in Cobalt. The silver production of the camp for 1907 was nearly 5 per cent. of the world's total.

The report should be widely distributed. It is the work of a capable, conservative and painstaking mining engineer.

A NOVEL COUPLING FOR MINE CARS.

(Copied from "Glückauf" 11th March, 1908.)

The coupling arrangement shown in the following cut has been successfully used for some time past in the Minister Achenbach Colliery at Brambauer, near Dortmund, Westphalia. No further details than those shown in the illustrations are necessary to explain the design,

the chief advantage of which is that both coupling members—the shackle and the hook—are together on each side of the car. To couple, the shackle of one car is placed horizontally and the hook is thrown over the circular end of the shackle of the other car. To uncouple the cars it is only necessary to press the hook upwards when both shackles will be released by their own weight. Any accidental uncoupling is impossible because the weight of the shackles in every position presses them together and holds the hook in place. The stronger the pull of the rope also the tighter the connection between the hook and the shackles. It is therefore impossible for uncoupling to occur through sudden bumpings or jolts of the cars, and the numerous breakdowns that occur from this cause are entirely obviated by the use of the arrangement under consideration, and by reason of the tight connection jerking is almost eliminated.

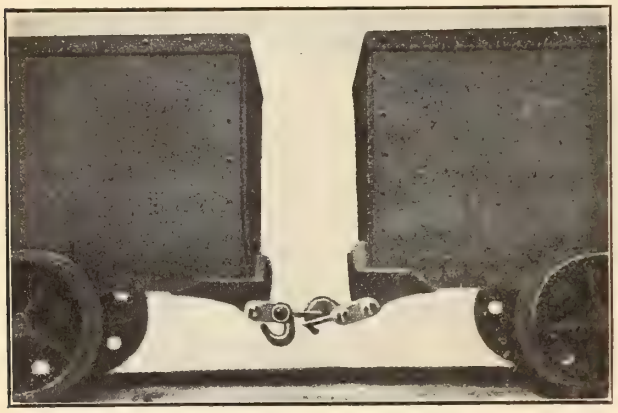


Fig. 1.—Coupling Attachment.

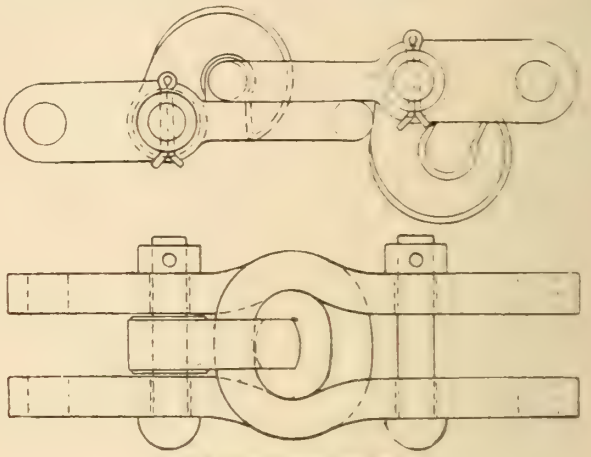

Fig. 2.—Side View and Plan

The coupling is made by the firm of Hugo Klever of Dortmund, and is easily attached to any form of mine car.

F. W. G.

HOW CAN THE GOLD INDUSTRY OF NOVA SCOTIA BE ASSISTED.

By E. Percy Brown, Goldboro, N. S.

(Paper read at Meeting of 25th March, 1908.)

Many of us believe that gold mining in Nova Scotia is about to experience a period of fresh activity on a surer basis than heretofore. We realize that many mistakes have been made in the past, and that the industry has received some bad blows from which it must take some time to fully recover.

I have endeavoured in a few short papers, written during the past year, one for this society and one or two others for The Canadian Mining Journal of Toronto, to set forth what I believe to be the basis of future success in gold mining in this province, namely, the location of "pay shoots" and the following of the same. We have had several instances of the well-defined zones of pay ores extending to considerable depths, examples of which are probably familiar to all, and I contend that in most cases, when rich outcrops have been opened on the surface, that the same continue in depth and their continuations could be followed if proper knowledge were employed.

As to the difficulties in the way of opening up such properties, the chief one consists of the fact that the areas are held by men who will not, or cannot work them, and who do not have to sell them. I believe that right here lies the secret of what is hindering our gold-mining industry more than all other things put together the high price of coal *not* included. I claim that so long without working them, by the payment of the nominal as men are allowed to hold areas for an indefinite time sum of fifty cents an area per year, so long will the mining industry of Nova Scotia be more dead than alive. The measures necessary to correct this may seem harsh. No doubt we would all suffer to a certain extent if a radical change were made in this direction; but I believe that all those who are vitally interested in the welfare of this important industry will see that such a change is necessary.

Why is it, may I ask, that gold mining, struggling as it is, has still to pay a tax on its output? Other kindred industries receive bounties, why not gold? Our coal-mining brethren will claim that they pay a royalty on their product. I ask: who pays this royalty? It appears to me that the gold miners not only pay the 2 per cent royalty on their output, but a full share of the 50 cents per ton on all the coal they use.

If a manufacturing company of any kind proposes to establish a plant anywhere in the province it receives certain privileges, such as a free site, free light, exemption from taxation for a certain number of years, etc. When a gold mining company proposes to start operations, it must first acquire the areas by paying for them probably ten times their actual value, as they lie undeveloped or condemned. The surface rights must be purchased, or the company runs the risk of having to pay excessive damages. When operations are underway they must bear the burden of taxation for the district and hand over to the government the two per cent. tax on their gross output, even if they run themselves into debt to do it.

Can there be any question as to the good that a gold-mining concern, properly conducted, does to a community? We have simply to compare the conditions as they were at any of our well-known mining camps, when in full operations, with what they are to-day when idle. What is more prosperous than the community surrounding an active gold mine? Take for example the settlement that has grown up in the vicinity of the Richardson mine at and near Goldboro, Guysboro county. This mine has been in operation for the past fifteen years, expending from $3,000 to $5,000 per month in the immediate neighborhood. Directly and indirectly the people within 20 miles on each side of this mine have derived great benefit from it, and there are not many manufacturing plants in the province that have benefited the people more than has this mine.

What encouragement has this mine received from the government or from the municipality? The Boston Richardson Company pays a very large proportion of the total school rates for the district; but when it asked that a school house be built close to the mine, so that the miners' children could avoid a walk of over two miles, its request was peremtorily refused. The company then built its own school house and furnished it at a cost of $700, accomodating fifty children that otherwise could not have attended school regularly during the winter months. They got no thanks and instead of a rebate in their school rates got an increase. The Richardson mine has produced, during its existence, almost one million dollars worth of gold, netting a royalty of nearly twenty thousand dollars. The county taxes for the past year amounted to about six hundred dollars.

As another instance of the help afforded a gold mine by the community, may be mentioned the case of a company that expended between one and two hundred thousand dollars in developing a water-power and erecting a plant. Had its operations been successful it would have continued to distribute three or four thousand dollars per month among the community. So grateful were the people near at hand for this expenditure of capital, that they brought suit against the company, claiming that it would ruin the trout fishing on their river.

It seems to be the general impression that gold mining machinery is admitted free of duty; but I have carefully studied the tariff and can find no material or machinery admitted free, except copper plates and automatic feeders, that is likely to be of any great use to the gold mining industry. Automatic ore samplers are on the free list; but I very much doubt if we will ever need to import one. Bullion furnaces are not likely to be imported, and when we have arrived at a stage when we need to import mercury pumps, amalgam cleaners and amalgam safes, we will probobly be quite willing and able to pay duty. Why this discrimination?

I know of one case where a gentleman was importing a set of assay balances valued at $150.00. He asked that they be admitted free of duty as they were for a cyanide plant. His application was refused by the department as it was stated that balances might be used for other purposes than those mentioned,—for use in a grocery store, for instance.

The government of this province has passed an act to encourage gold mining in Nove Scotia by assisting in the sinking of vertical shafts. I do not know of a single district where such a shaft will develop to best advantage the zones of pay-ore. Where this method has been tried it has resulted in a failure. The reason for this is that where zones of pay-ore are found they usually pitch at low angles, ten to thirty-five degrees in the strike of the vein, and a vertical shaft rapidly leaves them, making proper development impossible, or, at the best, very expensive. A system of cross-cutting has been suggested, but while I can see how this would prospect the ore-bodies, I cannot see how it would develop them.

I hold that the only proper way to develop the shoots of rich ore, which we know to exist in this province, is by getting in touch with the pay-ore and keeping in touch with it, probably by means of an inclined shaft.

The above points have been merely stated as they occur to me, and I am open to correction on any one or all of them; but what I do ask is that a committee of active gold mining men of this society be formed to consider these points which may be summarized as follows:

1. To collect data relative to the existence of well-defined pay-shoots in Nova Scotia.
2. To confer with the government regarding the holding of areas by people who will not work them.
3. To confer with the government regarding the abolition of the 2 per cent. royalty.
4. To consider the tariff in so far as it relates to gold mining machinery and supplies, and to determine if a revision be possible.
5. To confer with the government regarding an amendment to the present act concerning the assistance to be given to the sinking of vertical shafts, so that it may apply to the sinking of any shaft, vertical or otherwise.
6. To determine what other steps can be taken to encourage the gold mining industry of the province.

The success which has attended the efforts of this society to establish a system of technical education in Nova Scotia shows what can be accomplished when the proper steps are taken, and I believe that the above committee could be as fully successful in its undertaking.

In closing, I beg to suggest that Mr. E. R. Fairibault be a member of this committee.

ROCK DRILLS USED IN COBALT.

The tabulated list of power and drill equipments of Cobalt district, recently published in THE CANADIAN MINING JOURNAL, was as correct as could then be obtained. We are indebted to Mr. A. A. Cole, mining engineer of the T. & N. O. Railway, for the following corrected statement of the number and makes of drills:

Percussion—	
Ingersoll	56
Mac	73
McKernon	9
Rand	203
Sullivan	4
Total	345
Air Hammer	
Hardsoeg	2
Murphy	13
Shaw	1
Sullivan	2
Waugh	3
Total	21

As will be noted by comparing this with the former list, there are a few changes. Any person who has attempted to gather exact information of this nature will realize how difficult it is to obtain. It may be added that such information is of positive value.

THE MECHANICAL EQUIPMENT OF THE OTTAWA MINT.

(A paper read before the Mechanical Section of the Canadian Society of Civil Engineers.)

(*Continued from April 1 Issue.*)

Rolling.—When designing these mills arrangements were made to provide for extremely accurate and very fine adjustments for the rolls, for all the driving mechanism to be kept above the floor level (the ground being rock, and very hard to excavate) and for economy of floor space.

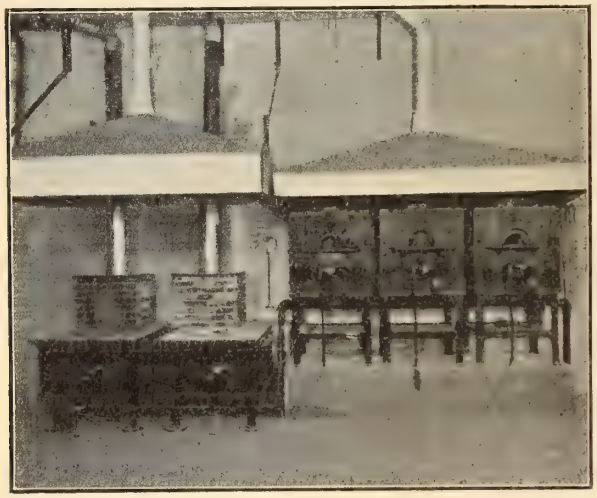

Fig. 6.—Cupel and melting furnaces in Assay Department.

Each mill is driven by its own motor, through gearing; the general arrangement being as follows:—

The motor, gearing and roll housings are all on one bedplate, thus ensuring rigidity and perfect alignment. The first motion shaft carrying the driving pinion runs

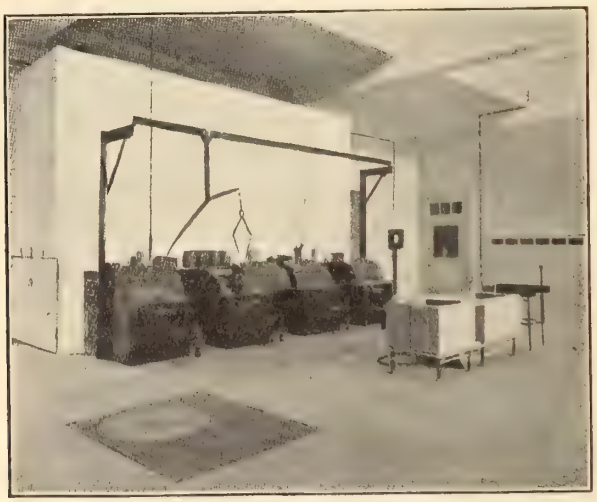

Fig. 7.—Melting furnaces, condensing chamber, acid and water tanks in Melting House. The granulating tank is situated under the iron plating shown at the left of the foreground, and is fitted with water supply, over-flow and waste pipes, and settling tank.

in its own bearings and, at one end, is connected with the motor through a flange coupling outside one of the bearings, so that the motor is entirely free from any thrust. At the other end of this shaft, outside the other bearing, a small fly wheel is keyed. The second motion shaft gears with the shaft driving the bottom roll, and this latter shaft gear through double helical gearing with the shaft which drives the top roll.

The rolls are conected with the gearing by means of breaking spindles and muff couplings. The couplings are held up to their work by adjustable wood distance pieces.

The motors run at 600 revolutions per minute, and the rolls at from 40 revolutions per minute, for the breaking down mill, to 60 revolutions per minute for the finishing mill.

The form of drive described above is found to be very convenient, and to absorb very little power.

The breaking down mill is driven by a 30 H. P. motor, fitted with an overload release, which is set to cut out at 50 per cent. overload. The distance between the rolls is regulated by means of worms and worm wheels actuating large, single, square thread screws of 1-2 inch pitch. There are 50 teeth in each worm wheel. The worm shaft is divided in the centre, the halves being conected by means of a friction coupling, so that when it is neces-

Fig. 8.—Shearing machine, rotary gas and assay crusher in Melting House.

sary to "parallel" the rolls, one end only of the top roll may be moved at a time. This worm shaft is actuated by hand wheels at either end, one complete revolution of which closes or opens the rolls .01 inch. The hand and worm wheels are fitted with indicators and divided circles, so that adjustment of the rolls can be made as fine as .0005 inch. For ordinary rolling it is usual to work to .001 inch at this mill.

It has been found difficult, with the form of adjustment detailed above, to prevent the top roll from jumping, when the bar which is being reduced first enters between the rolls. This jump may arise from the three following causes:—

(1) There may be slackness between the roll journals and bearings.

(2) There may be looseness in the attachments between the bottoms of the big screws and the caps of the roll bearings.

(3) There may be wear between the big screws and the threads of the nuts in the roll housings.

When it is remembered that the weight of the top roll with its brasses and adjusting gear amounts to about two tons, it can be readily imagined that signs of wear will soon become apparent between these nuts and screws.

Various devices have been tried with a view to prevent this jumping of the top roll; a common one being that of heavy weights, situated in a tunnel below the floor level, which act through levers and rods to counterbalance the weight of the top roll and gearing. This method, however, does not entirely overcome the difficulty.

In order to avoid excavating for a tunnel, the following arrangement has in this case been adopted, and there is every reason to hope that it will be entirely successful in preventing the jump of the rool.

The top of each roll housing has been extended on one side so as to form a hollow casing in which a powerful buffer spring is situated. Each spring is of sufficient strength to take, when half compressed, the entire weight of the top roll with its brasses and adjusting gear.

When the top roll is depressed to within one inch of the bottom one, these springs come into full play, and thus keep the big screws, which actuate the top roll in close contact with the upper side of the threads in the nuts. There is thus no weight on the bar that is being

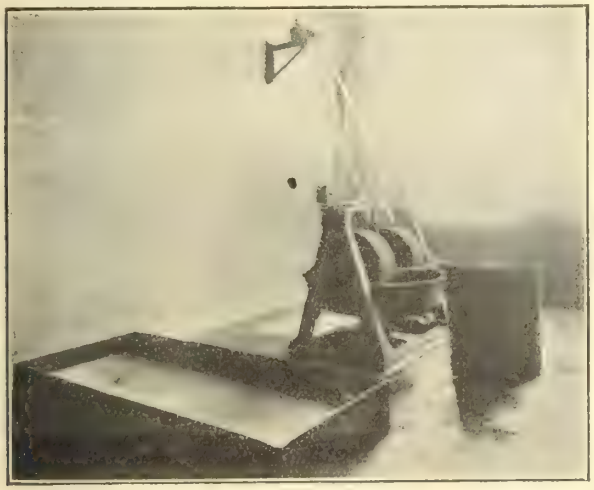

Fig. 9—Mortar mill for reducing worn-out crucibles, etc., for the recovery of precious metal.

rolled other than the intentional pinch given to it through the gearing.

This arrangement has been thoroughly tested and, up to the present, the top roll has shown no sign of jumping. The bars so rolled into "fillets" have been carefully gauged and found to be remarkably uniform throughout their entire length.

The rolls in this mill are 14 inches in diameter and 16 inches in length, and are driven at 49 revolutions per minute.

The thinning mill is driven by a 20 H. P. motor in the same manner as the breaking down mill. The adjustment of the rolls is also the same, but the gearing, etc., is, of course, of somewhat lighter construction.

The rolls in this mill are 12 inches in diameter and 14 inches in length, and are driven at 50 revolutions per minute.

The finishing mill is driven by a 10 H. P. motor in the same manner as the others; but the adjustment of the rolls is different. This distance between the rolls is varied by raising or lowering the bottom roll by means of long steel wedges, which are actuated by a hand wheel through gear wheels and fine screws . The hand and gear wheels are fitted with indicators and divided circles, so that adjustment of the rolls can be made as fine as .0002 inch.

Fig. 10.—Rolling mills. Fillet-annealing furnace on right.

The rolls in this mill are 10 inches in diameter and 12 inches in length, and are driven at 60 revolutions per minute.

The bars from the Melting Department are first passed 10 or 12 times through the breaking down mill, after which they are annealed in the fillet annealing furnace. They are then passed 8 or 10 times through the thinning mill and 5 or 6 times through the finishing mill, when they should be the correct thickness for the coin that is to be made. For silver and bronze coins, rolling is sufficiently accurate; but for gold, further treatment is necessary. This latter metal is very dense, having a specific gravity of about 19, as against about 10 for silver and about 9 for bronze. The variation alolwed by law from a standard weight is also, in the case of gold coins,

Fig. 11—Breaking down mill and fillet annealing furnace.

very small. For instance, the standard weight of a British sovereign is 123.274 grains, but the remedy allowance is only .2 grain. If the coin exceed this limit, by even so little as .01 grain, it is rejected, and re-melted. The remedy allowance on silver coins is much more gen-

erous, weight for weight; being between two and three times as great as for gold.

The fillet annealing furnace is heated by oil fuel mixed with steam at 60 pounds pressure per square inch. The floor of the heating chamber is composed of three endless chains, travelling side by side, and driven by sprocket

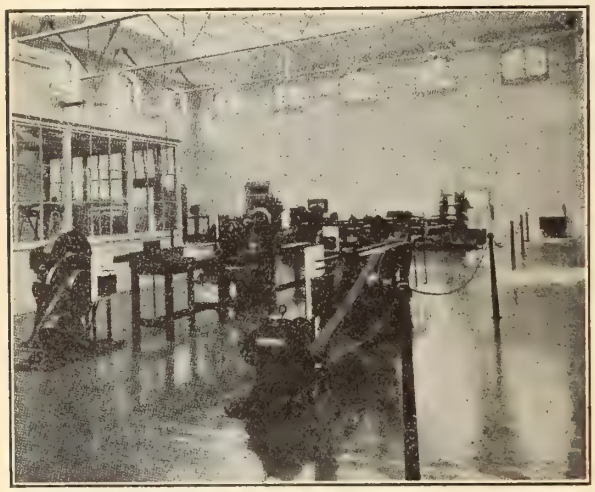

Fig. 12.—General view of Rolling and Adjusting Room, showing draw-bench, automatic trying cutter, and scale room.

wheels situated at either end of the chamber. The speed at which the chains travel can be varied by means of a speed box attached to the driving motor; so that the time occupied by a fillet in passing through the furnace may be from 4 to 12 minutes. The fillets are laid flat on the travelling chain, 5 or 6 side by side, and as they emerge, pass through a sheet of water; so that they are cooled before they come into contact with the air. This arrangement prevents oxidation, and very little, if any, discoloration is noticeable.

Adjusting.—In the case of silver and bronze, the fillets pass from the finishing mill to the blank cutting machines; but, in the case of gold, as before stated, it

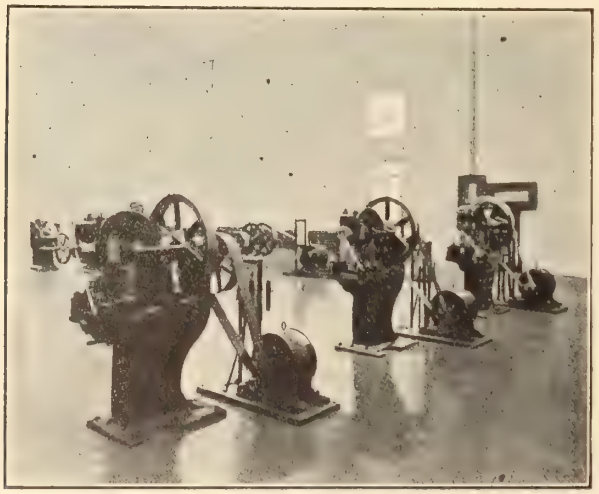

Fig. 13.—Cutting-out machines.

is found that further adjustment is necessary. The gold fillets are accordingly taken to the drawbench, where they are drawn between two fixed steel cylinders by means of a dog-clutch, which engages with an endless chain. These cylinders are about 4 1-2 inches long and 3-4 inch in diameter; they are highly polished, and extremely hard, and the distance between them can be adjusted to .0001 inch. By this means the small inequalities in the thickness of the fillets are regulated, and their variation from standard is reduced to a minimum. The fillets then pass to the blank cutting machines.

Cutting.—There are three of these machines, each one driven by a separate motor, and capable of cutting blanks for all sizes of coins, at the rate of 300 per minute. The punches and beds for all the different denominations are interchangeable, so that little time is occupied in changing from one to another. Each machine is fitted with an automatic variable feed, which can be increased or decreased by multiples of .05 inch.

After the blanks have been cut from the fillets, the skeletons that are left (technically known as "scissel") are cut up into convenient lengths, and made up into bundles for re-melting.

Marking.—The blanks are next taken to the marking machine, where raised edges are formed round their circumferences. These raised edges protect the impressions, which will be given to them later in the coining presses, and thus prevent their being rapidly worn

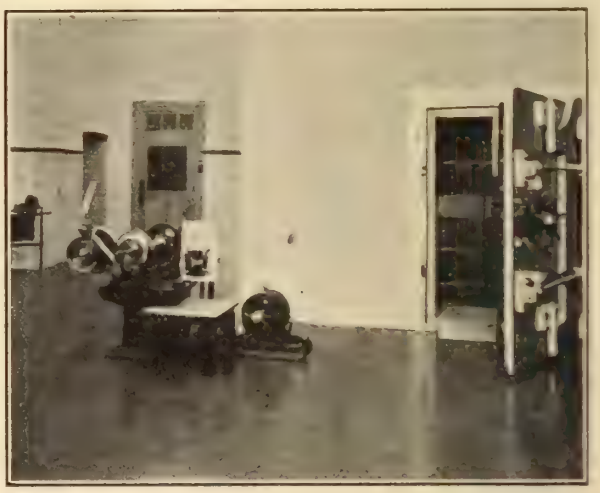

Fig. 14.—Marking machine and stronghold door.

away. This machine is capable of making 600 blanks per minute. The blanks pass between a circumferential groove, in a rapidly revolving hard steel disc, and another groove, struck from the same radius, in a fixed hard steel block. The distance between the disc and the block can be varied, so that any size of blank may pass between them. The blanks are then annealed, and thoroughly cleaned.

(To be continued.)

ALLOYS.

This is the age of alloys. Special research is constantly revealing unsuspected valuable qualities in new combinations of metals. Nickel steel, chrome steel and other high grade steel alloys have revolutionized the manufacture and use of structural material. The speed and durability of the modern motor car would have been unattainable had not special steel alloys been introduced. Foundry practice and machinery construction have been profoundly modified and improved by the intelligent use of alloys.

These considerations lend interest to a booklet issued by Geo. G. Blackwell Son s& Company, Limited, of Liverpool, Eng. This firm holds contracts with the British and many foreign governments. It specializes in alloys and metals. Under its control is the largest electric furnace works in the world, where a maximum of 42,000 horse-power is utilized. The firm also owns and operates its own mines. From the booklet a few facts may be quoted.

Chromium.—Ferro-chromium is used for armour plates, projectiles, wire, high speed steel, stamp shoes, and dies, tires and axles, etc. Its high percentage of chromium and its uniformity determine the value of an alloy. One brand made by the Blackwell Company shows the following analysis:

	Per cent.
Chromium	66.448
Iron	21.90
Carbon	8.800
Silicon	1.353
Manganese	Trace.
Phosphorus	0.053
Sulphur	0.045
Loss and undetermined	1.311
	100.000

As a contrast to this, and constituting in itself a metallurgical triumph, another variety of the same brand shows 69.30 per cent. chromium and only 1.47 per cent. carbon; and another 63.586 chromium and 0.65 carbon.

For making high class steels containing fixed percentages of chromium and nickel, a chrome nickel iron alloy is supplied. Its analyses is as follows: C, 52; Ni, 18; Fe, 28.96; C, 0.50; Si, 0.50; S, 0.03; P, 0.01. The low carbon is a most important feature of this and similar alloys.

Tungsten alloys, which are replacing tungsten metal powder, range from 85.79 to 65.70 per cent. tungsten, and from 0.60 per cent. carbon to 2.92 per cent.

Molybdenum is fast becoming recognized as one of the most valuable constituents of a steel alloy. It increases the elongation and elastic limit of steel. In this respect it is much more valuable than nickel. An addition of 0.25 per cent. of molybdenum increases elongation from 4 per cent. up to 45 per cent. This gives it great value in the manufacture of large crank and propeller shafts. Its introduction into boiler plates for high pressure boilers has made possible the use of lighter plates that are actually stronger than much heavier plates made without the alloy. For motor car forgings and castings molybdenum steel is specially adapted. In high speed tools it gives all the desirable qualities with carbon kept below 1 per cent.

Ferro-molybdenum ranges in composition from 85 per cent. to 50 per cent. molybdenum and from 3.07 to 0.35 per cent. carbon.

NOTES ON FUEL ECONOMY AND ITS APPLICATION TO NOVA SCOTIA.

By A. A. Hayward, Halifax.

(Read before the Mining Society of Nova Scotia, 25th March, 1908.)

Of late there has been abroad a spirit of dissatisfaction and unrest, one that has developed into a strong desire for something commercially better, an increasing desire for a larger share of continental prosperity, a hope that fate might drift the golden barge of prosperity near our shore, so that we might secure more of its precious cargo. There are those whose personal desires and patriotic dispositions have lifted them above political and party degeneracy, and by such this manifestation has been termed the "forward movement." For these and such others as are desirous of dipping deeper into industrial questions, I have prepared the following remarks:

Do we deserve to become commercially strong? If so, it is absolutely necessary that we select for our foundation naturally existing materials or conditions, and not those created by party force or individual craft. Natural conditions are created, not made. They constitute our natural resources, such as raw material, water power, fuel deposits, etc. If we are wise, and above all sincere, in our industrial and commercial aspirations, we will seriously investigate these conditions if we desire to build wisely.

It is sometimes said we are an extravagant and wasteful generation, and that through our mechanical and commercial recklessness we are securing but a sup from the horn of plenty and throwing aside the remainder of its contents. Behind us we leave a trail of neglected opportunities and wasted natural resources. As we run over the facts before us, the mass of accumulated evidence seems interspersed with instances of our supreme ignorance of natural conditions, as well as our neglect in applying the knowledge already in our possession. The only defence we offer for our course is that it is the result of the exigencies of competition and increased dividends on the production and distribution of the products of our raw materials. We are regardless of the moral and natural rights of the consumer, from whose birthright we are securing but a fractional part of the values contained therein. It does not require a close observation of events to see that we are selecting from our industrial tree only such fruit as is within easy reach, and from which we can, for the moment, secure the largest margin of profit.

Such in part are some of the regrettable facts conspicuously evident in a survey of this subject, conditions which justify the consumer in demanding an equitable share in the distribution of his inherited rights. Such an equitable distribution does not contemplate the securing a smaller percentage of the fruit of the industrial tree with the loss of the remainder, but the harvesting and marketing of a larger percentage, to the better advantage of both producer and consumer. If we are to enjoy the fullness of commercial prosperity, the ox should not be sacrificed for the hide and tallow alone.

During our mad rush for dividends and commercial supremacy, we have overlooked one of the most important of all fundamental facts, that is, that to mankind

in general belongs the natural raw material, and that while we have, by civil enactment, vested it in the hands of individuals, as custodians, it is incumbent upon the producer to secure and distribute the finished product to the consumer by the most direct means, and at the lowest possible cost. It is also incumbent upon the producer to recover, as far as possible, all the marketable commodities contained in the raw material, in order that he may cheapen the cost of the whole. It should also be his duty to protect the finished product from the commercial parasites that infest the highway from the point of production to that of consumption, by adopting as his trade-mark, "One common inheritance, one profit."

Does not the mal-practice with which we continue to manipulate the energy stored up in our great coal deposits furnish abundant evidence of the slowness with which we grasp the importance of more practical and economical applications of later-day mechanical devices and commercial methods. That we may more intelligently present our case, a single subject will serve to illustrate, and a specialization of the evidence will greatly assist in arranging our final conclusions. For convenience let us select as a representative subject, one familiar to all, namely, coal.

Nature has stored up in its coal deposits enormous energy, which we are rapidly consuming. In spite of the vastness of these fuel deposits there are those who recognize that materials containing such vital energy must be economized. We are not so rich that we can disregard the necessity for economy, and continue wasting what nature has so generously donated. Authorities all confirm the opinion that in the burning of coal by our present mechanical devices, we are wasting nine-tenths of the heat energy stored up in these fuel deposists. There are some who venture to predict the discovery of new sources of energy when these have been exhausted. The future is an unknown quantity and should not concern us at this time.

The question of economical generation of power and heat from fuel is the most serious and important one of this mechanical age; while its centralization and distribution require careful mechanical and commercial consideration.

Anyone sufficiently interested to follow the history of a ton of coal will see it mined at one profit, transported at another, handled and re-handled at an additional cost, and to this must be added the profit of the middleman, and he is forced to admit that all these various charges have been paid on at least 12 per cent. of ashes and stone contained in the coal. This picture of unnatural conditions must be sufficient to convince any student of economy that radical changes are absolutely necessary in our methods of production, transportation and distribution of our fuel product. It is estimated that forty per cent. of the fuel product mined is used for domestic purposes, and yet by the most improved methods of heat generation we have not succeeded in securing and turning into use 5 per cent. of its thermal efficiency. While from the balance, 60 p.c., if converted into power and light through the external combusion and steam engine, we have obtained remarkable results if we have secured 14 per cent.

A good average steam plant succeeds in securing and delivering at the engine shaft in useful energy from 6 to 8 per cent., while a modern compound condensing engine, working under favorable conditions and in large units of from 1,000 to 2,000 horse-power, may deliver in useful power from 12 to 14 per cent., thus sustaining an actual loss of from 86 to 94 per cent. of thermal energy contained in the fuel. Owing to the intensity in temperature of the superheated steam used in the modern high-power engine, the limit of its economic development seems to be nearly reached.

A series of tests made with steam engines in 1906 showed that the very lowest consumption of coal with the most improved steam plant was 1.03 per 1 horse-power hour, while five express locomotives consumed 3.16 pounds. The average consumption was placed at 5 pounds, although there were some that showed a consumption of 36 pounds per 1 horse-power hour.

Tests made of steam plants by the Automatic Gas Producing Company of New York gave the following results, and show the yearly cost to maintain 1 horse-power by the use of steam engine and boiler:—

Coal at $3 per ton, using 3 pounds per hour, $1,570 per horse-power year.
Coal at $3.50 per ton, using 8 pounds per hour, $4.200 per horse-power year.
Coal at $5 per ton, using 3 pounds per hour, $2,250 per horse-power year.
Coal at $5 per ton, using 8 pounds per hour, $6,000 per horse-power year.
Coal at $4 per ton, using 3 pounds per hour, $3,000 per horse-power year.
Coal at $4 per ton, using 8 pounds per hour, $4,800 per horse-power year.

It is not the purpose of this paper to describe in detail the gas producer and engine nor its mechanical operations, but rather by its well-recorded economical achievements to illustrate by contrast the opportunities that apparently await more energetic recognition.

European engineers have for some years recognized the pressing necessity for economy, and no scientific introduction is meeting with more approval from the engineering fraternity than the gasification of fuel and its application for heat, power and light through the internal combustion engine. German engineers long since recognized the economic and mechanical advantage of using gasified fuel as a motive force. England is partially awake, while American engineers, although somewhat behind, have begun to appreciate the merits of higher thermal heat as a means of developing power and light. European engineers and the public regard this principle with the same degree of confidence. Both large and small plants are in evidence everywhere. Large central stations, aggregating several thousand horse-power, are numerous, especially where economy is essential.

The use of gas for engineering purposes has greatly increased during the past few years, and to-day it is considered one of the most important means of generating power. Notwithstanding that other systems have been devised for power and light, fifteen million tons of coal are annually converted into gas.

It is well known that the efficiency of the internal combustion engine far exceeds that of the external. This economic efficiency is largely due to the constant improvements that have been and are still being made in both the producer and engine. Tramways and power stations are now being equipped with gas plants of large units, and builders are prepared to guarantee the performance of both producers and engines.

In Germany there are already installed 203 gas plants which have a total effective power of 184,000 horse-

power, while there are under construction and erection 146 engines which will develop 201,000 horse-power, making altogether 349 engines having a total power of 385,000 horse-power. Between the months of March and July there were ordered 31 engines, combining 36,150 horse-power. Of this total, 18,950 horse-power is to be used for generating electricity. Altogether in Germany there are 199 engines, combining 206 horse-power, that are being used for electrical purposes, the largest horse-power in any one plant being 35,000 effective horse-power. In 16 collieries there are in operation 35 gas engines, having 30,300 effective horse-power and most of these engines are used for generating electricity.

Large gas engines are gradually coming into use in England. The following figures will serve to illustrate the confidence English engineers have in the economic and satisfactory mechanical performance of producer gas plants. There were during the year 1906, 91 plants in operation, having 70,685 effective horse-power. None of these plants developed less than 500 horse-power. Six plants developing 3,660 horse-power received their supply of gas from blast furnaces. Four engines developing 2,300 horse-power were supplied from coke ovens. The balance, 62,019 horse-power, received their supply direct from gas producers. Coupled to many of the larger units are by-product recovery plants, for the saving of ammonium sulphate.

At Philadelphia, near Sunderland, there is a plant for supplying gas to an electric generating station, which in turn supplies current for the Sunderland tramway system. This plant is located at the pit mouth. At Park Head, Glasgow, Messrs. Beardmore & Company are operating a 20,000 horse-power plant. At Dalmire there is a plant generating 10,000 horse-power, 4,800 horse-power of which is used for generating electricity. At South Staffordshire, England, the Mond Gas Company has secured Parliamentary powers to supply Mond gas over an area of 120 square miles, distributing the same through pipe lines for heating and power, at a cost to large consumers of 4 cents per 1,000 cubic feet, and has installed a plant of 25,000 horse-power, consuming 250 tons slack per day. Messrs. Beardmore & Company have built and are building producers of 100,000 horse-power capacity, all of which clean the gas, and recover, as a by-product, sulphate of ammonia in sufficient quantities to pay the entire original cost of the coal. The Cargo Fleet Iron Company, Middleborough, have installed 24,000 horse-power with an ammonia recovery plant attached. Messrs. J. Brown & Company, Clydebank, have an 8,000 horse-power also with an ammonia recovery plant. A plan has been proposed for supplying the city of London with Mond gas from a plant to be located in the South Yorkshire coal fields. This will require a pipe line 25 inches in diameter and 175 miles in length. To assist transmission, the gas will be compressed to 500 pounds in compressors of 46,000 horse-power. It is estimated the cost of the gas delivered in the holders will be 15 cents per thousand cubic feet.

While electricity in Europe has replaced gas as an illuminant, the demand for coal has continued to increase. In addition to that necessary in generating electricity, the demand for gas for power purposes has increased faster than illuminating gas has been replaced by electricity.

In illumination fifty per cent. more illuminating power can be secured by converting gas into electrical energy than by burning the same in an ordinary gas burner. The ordinary gas burner only gives about 3 candles per cubic foot of 16 candle power standard quality gas per hour, while the modern gas engine coupled to a dynamo supplies one electrical horse-power on 19.8 cubic feet of illuminating gas at the rate of 26.5 cubic feet of gas consumed per kilowatt hour, giving off in electrical illumination 266 candlepower hours, equalling nearly four times the illuminating effect of the same gas burned in the ordinary flat gas burner, or equal to 10 candle power hours per cubic foot of gas burned.

(To be continued)

LOVE AND PETROGRAPHY.

Lines suggested by a conversation with the Petrographer of the Geological Survey, who was examining rock slides.

Visitor: "Come, throw those wretched slides away
and give ourselves to other thoughts,
Let's seize upon this summer's day
To drink the cup of joy in
Petrographer: Quartz.

Visitor: "Has life no other aim but this?
Discard your work—there's time enough!
Let's seek for love—and, seeking, kiss
The maiden when we find her
Petrographer: Tuff.

Visitor: "Holds love no joy for such as you?
Your rocks of stone! your heart of ice!
What if a loyal heart and true
Should prove some day that love is
Petrographer: Gneiss.

Visitor: "Let others prate of wealth, and might
Of conquering heroes, power and place—
Than die a nobleman to-night
I'd sooner live to
Petrographer: Diabase.

—F. J. N.

Economic Geology, March-April, 1908.—In a paper entitled "A Practical Classification for Low Grade Coals," Marius R. Campbell brings out these points:—

(1) The recognition of two classes of coal below the grade of bituminous.

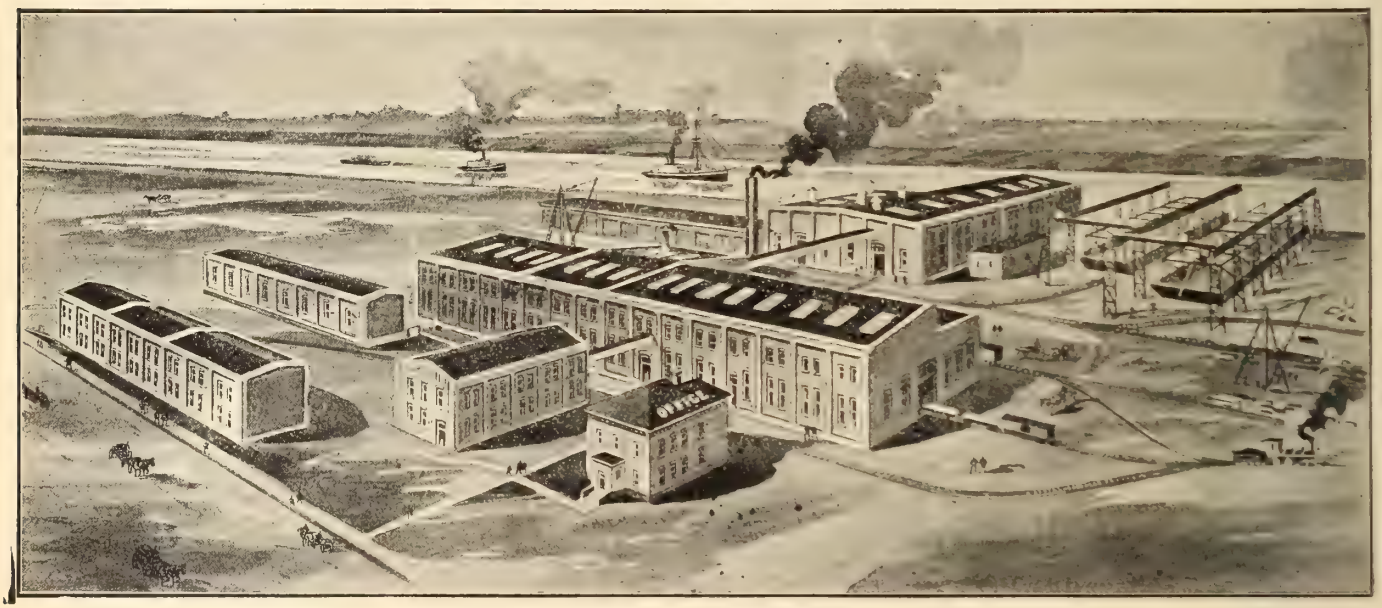
(2) The restriction of the name "lignite" to the lower grade, and the application of the name "sub-bituminous" to the higher grade, in conformity with the usage of the United States Geological Survey.

(3) The recognition of weathering as the criterion for separating the sub-bituminous from the bituminous grade of coal.

(4) Manner of weathering divided into two classes: (a) Irregular breaking in sub-bituminous coal as opposed to cleaving into prisms in bituminous coal, and (b) separation along bedding planes into plates in sub-bituminous coal.

(5) Separation of lignites from sub-bituminous coal on the basis of color, the former being brown and the latter black.

INDUSTRIAL PAGE.



A LARGE CANADIAN PLANT.

Almost exactly a year has elapsed since M. Beatty & Sons moved into their new factories and offices on Muir street, Welland, Ont.

Founded in what was then the village of Welland, in the year 1862, by the late Matthew Beatty, of Londonderry, Ireland, the concern is now one of the most progressive in Canada. Its superbly equipped plant occupies a frontage of 1,100 feet on the canal. The various buildings are of the most modern type of steel and concrete construction. The plant and yards cover fifteen acres.

The first complete dredge ever constructed in Ontario was built by M. Beatty & Sons. As manufacturers of contractors' supplies, the firm's reputation is unique. Their products include dredges, derricks, steam shovels and hoists. These are adapted to the needs and requirements of Canadian conditions. The firm's long experience has enabled them to turn out machinery that is unsurpassed in strength and fitness.

Main Building.—This structure is 80 x 324 feet, is built of concrete and steel and contains the machine shop, casting room, store room, core room and cupola room. In the machine shop, 80 x 160 and one storey high, the erecting department occupies the east side. A fifteen ton Niles travelling crane runs the entire length of the shop. The shop is equipped with a large boring mill, radial drill, cold saw, horizontal boring machine, etc. The crane and eleven large machines are driven by individual

PLANT OF M. BEATTY & SONS, WELLAND, ONT.

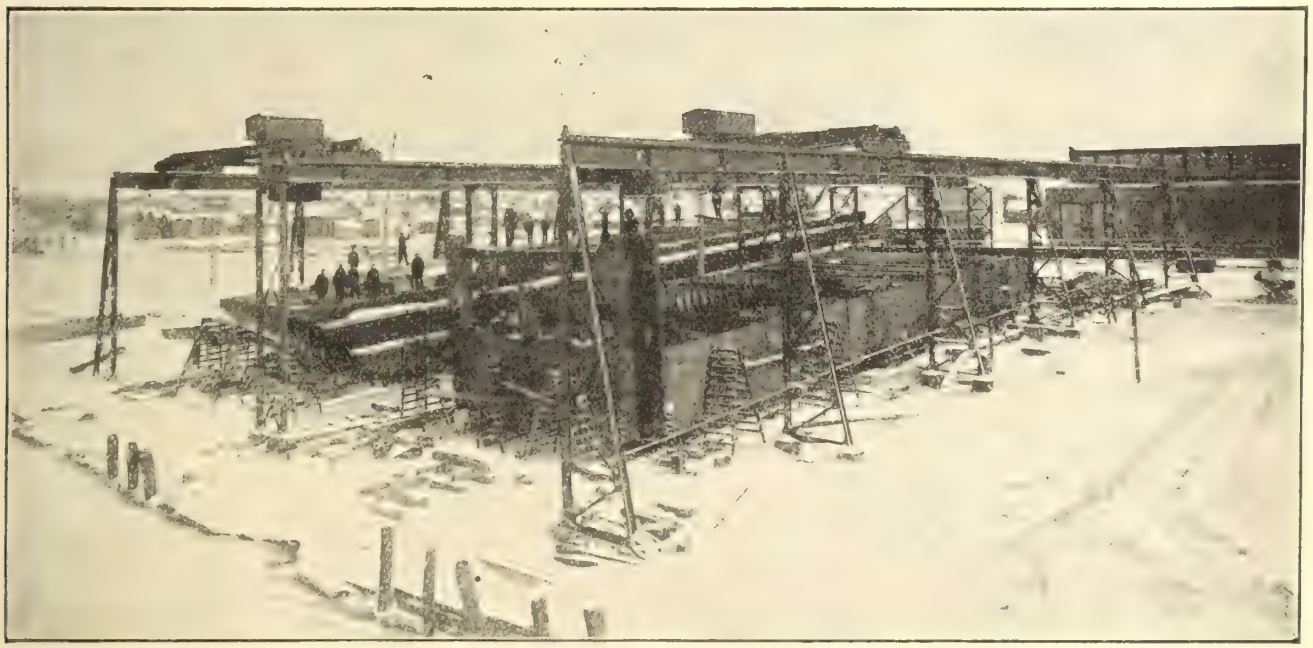
MACHINE SHOP OF M. BEATTY & SONS, WELLAND, ONT.

variable speed electric motors. On the west side of the shop, where the light machinery is assembled and erected, a jib crane on overhead tracks does all the handling, and a forty horse-power motor drives the machinery. A standard gauge railway runs through the centre of the building.

The foundry store department is two storeys in height. In the lower storey castings are stored; in the upper storey the heating apparatus is installed and the finished parts are stored.

The foundry department, 100 x 80 feet and one storey high, includes two ten ton Nile cranes with individual motors, a Colleau cupola of five tons per hour capacity, a fan driven by a 30 horse-power individual motor, and two Kinnear patent core ovens heated by natural gas.

Boiler Shop.—This one storey building, constructed of concrete and steel, is 50 x 101 feet. Boilers are made here and all materials for the steel hulls of boats and dredges. Two five ton travelling cranes are used here. The building is fully equipped with shears, punching machine, heavy boiler rolls and a radial drill.



Pattern Store House.—Of concrete and steel, two storeys high, 42 x 144, built in three compartments with concrete fire walls.

Office.—The office, also, is concrete and steel. The building measures 36 x 50 feet, is two storeys high and is finished inside in Georgia pine. Downstairs there are five offices; upstairs, two draughting rooms. On each floor there is a fireproof vault.

Machinery Store House.—Concrete and steel, 36 x 144, one storey.

Power House and Power Equipment. — The power house is a one storey building, 32 x 72 feet, concrete and steel. The roof is also of these materials. For heating purposes a 130 horse-power boiler is installed here. Two air compressors, one with a capacity of 341 cubic feet of free air per minute at 160 revolutions and the other with a capacity of 251 cubic feet are to be seen here.

Power is received from the Cataract Power Company at a voltage of 2,200, and is transformed down to a working pressure of 220 volts.

SHIPYARD OF M. BEATTY & SONS, WELLAND, ONT.

Shipyard.—The shipyard is situated on the bank of the canal at the north end of the boiler shop. At the launching slip two steel towers are erected, 35 feet high, 160 feet long, with a span of 50 feet. One ten ton Shaw travelling crane handles the material. A subsidiary crane handles material from the cars to the launching slip. Compressed air is used for caulking and riveting.

Blacksmith Shop.—The building is 51 x 61 feet, one storey, concrete and steel. Six forges are operated. Each has an improved adjustable hood and an 80 inch fan to carry off smoke. Other features are one 1,100 pound steam hammer, one 250 pounds Beaudry hammer, four three ton jib cranes, and one crane outside the shop.

Carpenter Shop and Patternmakers' Shop.—This is a two storey building of concrete and steel, measuring 42 x 82. In it are a dry kiln 22 x 24 and a vault for storing shavings, 6 x 24. The shavings from each machine are removed by an exhaust fan and deposited in the vault. All patterns are made here.

Both alternating and direct currents are used throughout the different departments.

Compressed air is used in all the departments for chipping, riveting, drilling, boring, etc.

There are eight or ten other buildings, not including lumber shed. All the large buildings are so constructed as to be easily enlarged as business may warrant.

B. F. Sturtevant & Company's heating system is used. Ventilation is perfect. Each department is provided with modern sanitary lavatories.

On the company's ground are 3,300 feet of standard gauge railway, and 3,000 feet of industrial railway.

Catalogue No. 2 of the Triplex Rolls Company has been received. The headquarters of this company are the Boston Building, 1650 Champa street, Denver, Colorado, U.S.A.

In the Triplex Rolls an entirely new departure is roll construction has been undertaken, viz., the insertion of a third and larger roll between the faces and at right angles to the two rolls as ordinarily used. This gives two grinding faces instead of one, as heretofore. Also the grinding faces are kept true automatically. Further, the elimination of grooving means that the product is uniform and that no oversize occurs. The twisting action, caused by the cross directions of the opposing faces, produces a granulating effect; and the smaller angle of nip produces a grinding zone of more than twice the area obtained in the old style of rolls. The Triplex Rolls are therefore to be recommended for their large capacity for fine and uniform grinding. They are not, in any sense, roughing rolls. Their manufacturers claim that a finished product of 40-mesh and finer may be obtained continuously throughout the life of the shells. The item of saving in tire renewals is also of importance.

CATALOGUE OF THE W. S. TAYLOR COMPANY, CLEVELAND, O.

To an ever increasing degree mine managers, and technical men generally, depend upon trade catalogues to keep constantly in touch with the latest and best machinery and accessories.

We have just received from The W. S. Tyler Company of Cleveland, Ohio, their catalogue Number 24—an excellent specimen of the printer's and engraver's art. It contains carefully arranged illustrations of the uses of woven wire and correct lists, weights, and tables relative to wire cloth, with accurate dimensions in decimals of the mesh—a feature originated by this company for the purpose of comparison.

The Tyler Double Crimped Wire Cloth is specially constructed, both as regards material and design, for long service and hard wear.

For use in stamp batteries, jig screens and trommels the Tyler Double Crimped Mining Wire Cloth has a capacity nearly double that of punched slot screens. The openings are square and uniform and the double crimp insures the integrity of the mesh.

Wire cloth to suit all requirements may not be found in the catalogue. But the W. S. Tyler Company is prepared to meet special and individual requirements and specifications.

Particular mention must be made of their rolled slot screens for stamp batteries and rotary mills. The company issues a special catalogue describing this type of screen.

In mining practice, where the acidity of the water shortens the life of the screen, phosphor bronze wire cloth may be obtained. Its initial cost is high, but its long life means a substantial ultimate saving.

The heavy revolving screens made by this company are also of extremely substantial construction.

Bulletin 31 of the Hyatt Roller Bearing Company, of Newark, New Jersey, is devoted to descriptions of the Hyatt Bearing and the Standard Hyatt Bushing. The roller of the Hyatt Roller Bearing is made from a strip of steel wound into a coil of uniform diameter. Its flexibility results in an even distribution of load on the roller itself. All tendency to distortion of any of the bearing faces is done away with. The roller also, from its construction, acts an as oil reservoir and largely simplifies lubrication. The Standard Hyatt Bushing now manufactured in a number of standardized sizes, is designed for all conditions of speed and load, and for all classes of machinery.

BOOK REVIEWS.

TECHNICAL METHODS OF ORE ANALYSIS—BY ALBERT H. LOW. THIRD EDITION, REVISED AND ENLARGED. 8 VO. XII. + 344 PAGES, CLOTH $3. JOHN WILEY & SONS, NEW YORK.

Within a little more than two years, Mr. Low's book has run through two editions. The third, a marked improvement on its predecessors, has now appeared.

Numerous incidental changes are apparent. But radical alterations and additions have been made in the chapters on aluminium, antimony, arsenic, calcium, lead, magnesium, nickel and cobalt, tin, uranium and vanadium, zinc, coal and coke.

The direct method for aluminium, described in Chapter IV., is clean, delicate and rapid. It may be made more rapid, indeed, by omitting one or two of the steps that Mr. Low recommends. An important foot-note appears on page 21. After the addition of sodium thiosulphate in presence of sodium phosphate to the acidified solution, Blair recommends boiling for 15 minutes. Mr. Low's foot-note mentions that he has found 30 minutes safer. With this the reviewer concurs. The longer period is especially necessary when the precipitate is large.

The chapter on copper is given added interest by the fact that the original methods of Mr. G. A. Guess are quoted at length and the Guess-Haultain electrodes, for the design of which Mr. H. E. T. Haultain was responsible, is described. Mr. Guess elaborated the method.

The commercial methods for coal and coke are well outlined. It may, however, be pointed out that much more constant results can be obtained with the Chaddock burner in the determination of volatile combustibles, than with the ordinary Bunsen burner. Mr. Low omits mention of the use of blast for the first three and one-half minutes. This conforms with the experience of many chemists. The use of the blast is a fruitful source of error.

In a note is mentioned the serious mechanical loss consequent upon the application of a full flame to lignites carrying high percentages of volatile matter.

Harking back to the chapter on lead, we notice that Mr. Low gives half a dozen methods but does not hint at the electrolytic method now coming more and more into vogue. In this method the lead is deposited on the anode as lead peroxide from nitric acid solution. This was first used for commercial work some thirty years ago in the Mannsfeld Laboratories in Germany. Mr George A Guess was the first chemist on this continent to use it for routine work. In 1904 Mr. Guess made it the standard method for lead determinations at the Silver Lake (Col-

orado) laboratory. It is the simplest and by far the most accurate of all methods, and its value does not depend upon the skill of the chemist.

Mr. Low's book is, perhaps, the most usable volume of its kind that we know of. It is written by a man thoroughly acquainted with the difficulties that beset the commercial chemist. Already it is an accepted standard—a position that it merits and will continue to hold.

LEAD REFINING BY ELECTROLYSIS—BY ANSON GARDNER BETTS. 8 VO. IX. + 394 PAGES. CLOTH, $3. JOHN WILEY & SONS, NEW YORK.

The electrolytic refining of lead bullion is now an established metalurgical process. The volume before us is an exhaustive and reliable treatment of the subject. Electrolytes, slime treatment, deposition of antimony from fluoride solution, refining doré bullion, refinery construction, treatment of lead containing by-products, are among the subjects treated. Three pages are devoted to a bibliography.

There are three appendices, the first of which describes the plant of the Consolidated Mining & Smelting Company of Canada, at Trail, B.C. The lead refining plant at Grasselli, Lake County, Indiana, is described in the second appendix, and in Appendix III. the treatment of lead refinery slime is dealt with.

A noticeable feature of the book is the care with which the author has incorporated practical working details.

PERSONAL AND GENERAL.

Mr. H. E. T. Haultain, who has recently spent some weeks in Cobalt, returned to Toronto on the 19th of April.

Mr. H. C. Burchell, vice-president and managing director of the Sydney Cement Company, paid a short visit to Toronto on the 20th and 21st of April.

The class day address to the class of 1908 of the Michigan College of Mines will be delivered Friday, May 1st, at the College gymnasium by Dr. Charles Richard Van Hise, president of the University of Wisconsin. The class dinner will take place the following evening.

Mr. W. F. C. Parsons, mining engineer of the Londonderry Iron & Mining Company, and Mr. W. Selkirk, of London, Eng., pased through Toronto on April 11th, after a brief visit to Cobalt.

Mr. George H. Doran, managing director of the Foster Cobalt Mining Company, has returned from a visit to Europe, where he interviewed many the leading ore buyers and operators of smelters.

The analytical, assaying and testing business in Montreal, which has for years been conducted in Montreal under the name of "Milton L. Hersey," he recently been re-organized and enlarged. The "Milton Hersey Company, Limited, Chemists, Engineers and Inspecors," is now a joint stock company, of which Mr. Hersey is president, Mr. C. L. Trimingham vice-president, Mr. C. R. Hagen second vice-president, and Mr. Joel B. Saxe secretary-treasurer. In addition to their offices and laboratories at 171 St. James street, Montreal, a physical testing laboratory has been opened.

SPECIAL CORRESPONDENCE

Nova Scotia.

GLACE BAY.

Mr. Neil Gillis, he local member for the Provincial Parliament, on the 14th April asked for a Commission to investigate the question of an eight hour day for miners, similar in character to the Commission that was appointed to deal with the question of old age pensions. Mr. Gillis gave several reasons in favor of an eight hour days, first that it would minimize the danger to life and health of working underground. He said that the dangers to health from working underground were well known, and instanced the legislation now under way in England and other countries.

The contention that work underground is detrimental to health has been repeated so often that, except by those who know to the contrary, it is accepted as a fact without question. It has in fact become a shibboleth that is glibly repeated by many people, and there is a general tendency to commiserate the unhappy lot of those who in popular parlance "toil in the bowels of the earth." This sentiment is to a certain extent an echo of the terrible and miserable conditions that used to exist in coal mines in England and Scotland before the passing of the Coal Mines Regulation Act. If any person should wish to read a chronicle of unmitigated sordidness, a record of human greed and slave-like ignorance, of the murder of children and the degradation of women, let them read the evidence that was taken before the Royal Commission of the seventies, just before the passing of that monumental and satisfactory piece of legislation—the Coal Mines Regulation Act of 1870. There are graves of children all up and down the mining districts of England who were killed in the mine. One grave in Silkstone churchyard, Yorkshire, tells of the drowning of twenty-one children, ten boys and eleven girls, whose ages ranged from seven to sixteen, who were at work in the mine. Tales were told before that Commission of girls of tender years who worked half naked in wet and muddy mines, dragging boxes of coal on the pavement without rails by chains attached to the box and passed around their necks. At that time the life of the miner was one of sordid misery and ignorant debauchery, and what underground conditions were like may be gathered from the obelisks and monuments that are scattered throughout the English mining towns telling of the hundreds and thousands laid beneath who died in explosions in the mine.

But conditions have changed since that almost forgotten day. The miner, the "coalier" as he was called, was the last man in the British realm to receive the franchise, but to-day he polls the most telling and solid vote of any section of the working community. What are the actual conditions of life underground to-day? First of all, the miner works probably the shortest hours of any workmen, and also the least number of days. It is very rarely that a miner works more than five days a week, and in very few places, whether the eight hours bill is law or not, does he work more than eight hours a day. He receives high wages, particularly in this part of the world. The conditions under which he works are not, despite all assertions to the contrary, the most inimical to health. Compare the conditions of underground life with those of the alkali worker, the file-cutter, the tailor, women workers in factories and shop, with that of an engine driver on the railway, a stoker in a modern battleship or stoking an ordinary boiler. Compare it for hours with the dress-makers in large cities and the girls employed in huge departmental stores, with the ordinary surface day laborer or the ordinary everyday clerk. There is a great deal of uncalled for sentiment talked about the hard lot of the miner, for which there is no warrant. Statistics are against the popular belief, both mortality and sickness certificates,

and the refusal of insurance companies to insure miners at ordinary rates is not based on a belief that they are the subjects of ill-health, but on the recognized dangers to their lives from accidents which may involve a large number of men at one time. When at work underground the miner is in an equable temperature, not exposed to any of the weather vagaries. Every winter in Cape Breton the surface laborers around the Steel Works flock to the mines to get work under cover, where they are safe from the bitter blasts of our drift-ice cooled atmosphere.

As to the application of an eight hours Act in Cape Breton, the chief objection from the view of the operators would be the further limitation of an already limited season. The only way in which the Cape Breton operators could get the full output out of their mines and properly utilize their machinery would be to work three eight hours shifts per day, but this would necessitate night work. The P. W. A. object to night work, which they consider is even more debilitating than the ordinary work of a miner, and they asked recently for a one-quarter of a cent per ton increase for night work. Such a distribution of the work would produce a very acute situation when the shipping season ended and the collieries went on slack time for the winter. Under the present method of working this sudden diminution of the organization around the collieries at the end of the shipping season has been practically abolished, and this season the amount of double shift work that is being done will be the least of any previous season for a long time past. The fact, however, cannot be got over that the St. Lawrence is the market of the Cape Breton coal field, and that access to the St. Lawrence is barred from the middle of November to the middle of May. This is the problem of the operators, and it is also the problem of the miner. An eight hour day will not help to straighten it out.

In England the eight hour day bill is being forced through the House of Comons by an unwilling Government, against the expressed wishes of the whole community outside of the miners themselves, and against even the wishes of a section of the miners also. The statement of the English operators that it will necessitate an increase of 50 cents per ton in the price of coal has not been disproved. An increase of this amount will mean an increase in the manufactured cost of iron and steel of from $1.25 to $1.75 per ton. The effect of such an increase in the price of raw material can easily be foreseen on the English iron trade. The iron trade in England is the great customer of the coal trade, and unless one is prosperous the other must decline. If the eight hours bill is forced through the Houses of Parliament, not only will the English coal miner suffer the pinch of poverty, but his comrades in the iron trade and other trades will know the meaning of adversity.

Nova Scotia is perhaps the Province of Canada that is most closely allied by blood and by tradition to the Mother Country, and the Legislature of this Province has always followed closely the trend of legislation in England. At the present time, however, England is confessedly experimenting in class legislation, and some persons of eminence and learning, not necessarily prophets of evil, say that she is riding to a fall. Nova Scotia would do well to wait and see what happens before she enacts legislation that may very seriously hamper her industrial development, and for which there is no necessity.

The first ship to leave Cape Breton for Montreal this season was the "Norfolk," which cleared from Louisburg on the 9th April, bound for the St. Lawrence. The "Ellen" left International Pier on the 15th for the same destination, and in all probability she may reach port before the "Norfolk," as the latter vessel was detained in the drift ice off Canso.

Regarding the talk about amalgamation of the P. W. A. with the U. M. W. A., we notice Seaside Lodge, Port Hood, passed a resolution pledging themselves to stand by the P. W. A. and calling upon its members to resist the attempts that are being made to disrupt it. The Golden Rule Lodge, Dominion, have declared against amalgamation, and Equity Lodge, Caledonia, refused to discuss the matter. The 'Sydney Daily Post," for some occult reason best known to itself, has recently published several articles which might have been written by the walking delegate of the U. M. W. A. With this single exception the press has been unanimously hostile to amalgamation talk, and in this it has represented the concensus of public opinion. The "Post," however, has never regarded Glace Bay nor its industries with a friendly eye, and it never seems to remember that everything that hurts the industries of Glace Bay must react on those of Sydney. Such counsel as it is wont to give to its readers in the colliery districts may act as a boomerang some day.

Ontario.

Cobalt.

Silver Leaf.—The big vein shows up better at 125 feet than it has since the shaft was started. The main vein, which is twelve inches wide in the bottom of the shaft, carries remarkably high values. Two additional veins have been encountered. A 35 ton car of "A1" ore is being loaded. The management estimate the ore to run between six and seven thousand ounces to the ton. One car of low grade ore has been sent to the dry concentrator and over a car load is at the mine ready for shipment. A suit has been instituted by D. W. Maguire, as secretary of the Silver Leaf Mining Company, against the firm of Douglas Lacey Company, brokers, for the recovery of the returns from the sale of treasury stock of the company, sold by defendants and not accounted for to the company. The amount involved is $167,000.

Silver Queen.—A 22 ton car of ore was shipped to Copper Cliff on the 20th ult., which is expected to average five thousand ounces to the ton. The foundation for the new twelve drill Rand compressor is being prepared.

Colonial.—An important strike was made here last week. In driving in No. 4 tunnel a vein of native silver and calcite, 6 inches in width, was struck, the Tunnel had been driven in on a small seam of little value, but on putting a hole in one wall this rich vein was found. It has already been opened up for a length of 90 feet or more.

T. & H. B.—The crosscut driven north from the shaft has cut the "cobalt vein." This vein occurs at the contact of the conglomerat and keewatin and on the surface showed three feet of smaltite carrying little value in silver. Where cut below it carries silver, smaltite and niccolite.

Silver Bar.—Work has been resumed here. A shaft is being sunk and is now down 25 feet. In the bottom the vein is four inches in width and will average four thousand ounces.

Crown Reserve.—A car of 20 tons of remarkably high grade ore is ready for shipment. It is estimated to run from eight to ten thousand ounces silver. The vein from which the ore was taken is probably the richest so far uncovered in the camp, and one of the widest in the Cobalt district. A party of the directors of the company visited the property on April 11th.

Nipissing.—Mr. T. R. Drummond has left and Mr. R. B. Watson is now in charge here. Mr. Drummond was well liked throughout the camp, and before leaving the mine managers and some of his friends presented him with a silver tea service. The working men at the mine gave him a gold headed cane. The report for March shows that during that month there was mined ore to the value of $105,347 and 125.3 tons shipped with a value of $145,510. The ore available on April 1st is given at a value at $935,000. On January 1 this was given at $1,057,000, so this means a decrease of $122,000. The shaft on the Kendall lead is down 135 feet. The vein in the bottom runs from three to five hundred ounces per ton and is 5 inches in width.

Kerr Lake.—This company is, like many others here, sending shipments to different parts of the world to see where they will get

the best results. They are about to make a shipment of 100 tons of high grade ore to the Beer Ganheimer Company of Hamburg.

LARDER LAKE.

The Maxwell-Harris mill is running and the first brick, valued at $450, has been brought down from there.

At the Reddick, Mr. W. M. Ogilvy is in charge and supplies for four months are being rushed in before the snow goes. The 20 stamp mill, which has been on the ground for some time, is being set up.

MAPLE MOUNTAIN DISTRICT.

Supplies and equipment are being rushed in to the White properties at Maple Mountain. A small boiler, pump and hoist have already gone in together with lumber, etc., for construction purposes. A large compressor plant will be sent in as soon as navigation opens. These claims have been bonded by an English syndicate and are under the management of Mr. R. W. Foster, M.E., of Cobalt.

THE STRIKE SITUATION.

Botley, the union secretary, addressed the crowd in the square on Saturday evening. He told the workingmen that last year's strike had never been called off, that through stress of circumstances they were compelled to work this past winter in "unfair mines," but now that spring had come they should quit work, and any who still worked would be considered as enemies of organized labor. Not more than fifty men in the whole camp left their work and those that did were mostly men who had worked in the mines for the winter and were glad to go back to their farms. For every vacancy at a mine there are dozens of applicants who want work. No public meetings in the square will be permitted this year.

British Columbia.

ROSSLAND.

The mining men at this point are looking forward to a meeting of the Canadian Mining Institute, which will be held here on May 14th and 15th. Several technical papers will be read and discussed and other Institute business will be given consideration. Young mining men here are showing interest in the idea of a mining school being connected with the proposed Provincial university. An institution of this character would be a great aid to the rising mining men of the Province, and it is hoped that in due time it will come to pass.

Rossland continues to look with hopeful eyes toward the South Belt, where considerable prospecting and development work is being executed. The Blue Bird tunnel is now in over 70 feet, and the ledge shows up 4 1-2 feet wide in the face. The ledge appars strong and well defined, and the prospects are good for its downward continuation. The lessees are storing ore in the Homestake bins and now have 50 tons on hand, which will be shipped as soon as the spur is fitted up. Work has been commenced on the Pot, Alberta and Sunset claims. Development on the Giant-California is showing good results.

The following ore shipments were made during the week ended April 4th:—

	Week.	Year.
Centre Star	3,960	46,598
Le Roi	1,680	23,734
Le Roi Two	490	8,418
Evening Star	31	428
Iron Horse	38	38
Blue Bird	....	30
Total	6,199	79,246

The shipments for the week ending April 11th only amounted to 5,350 tons, the first three mines only shipping.

The Trail smelter received 6,150 tons of ore during the week ending April 11th. Besides the Rossland ore the following mines contributed to this tonnage: Rambler-Cariboo, 66 tons; North Star, 71; Scerro Verde, 9; St. Eugene, 536; Whitewater, 43; Eva, 23; Snowstorm, 468; Silver Cup, 33; First Thought, 294; True Fissure, 32 tons. The Trail smelter is now producing 20,000 tons of lead per annum, also copper mater, 999 1-2 fine silver, and gold bullion. The copper matte is shipped to the Tamoca refinery, the silver to Ottawa, New York and Hong Kong, and the gold to Seattle.

As will be seen by the above table of shipments, the Iron Horse has joined the list of shippers. This property adjoins the Enterprise, of the Consolidated Company, and has a good showing in the workings. The property has been leased to Rossland men by C. F. Jackson, the managing director, of Spokane. The ore runs from $14 to $38. Only four men are working on the property at present.

Smelter men here will watch with interest the results of the car of Cobalt ore sent to the Trail smelter from the Nancy-Helen mines. It is to be hoped that the freight and treatment charges will be found low enough to allow of continued shipments.

PHOENIX.

Phoenix received a visit from Richard Merton, of Frankfort-on-the-Main, Germany, last week. Mr. Merton is closely connected with the Metalgesselschaft, a company that deals extensively in copper, silver, zinc, lead and other metals. Mr. Merton was much interested in what he had seen of the mining industry of British Columbia and stated that during his travels he had seen nothing that compared with the Granby workings as far as low costs and economical operation were concerned. It was his opinion that copper would gradually rise to what should be its normal price, 17c or 18, as soon as the financial sky had cleared up and the manufacturers were again receiving steady orders.

The Granby shipments were somewhat lower during the week ending April 11th than what they had been for some time previous to that. The shipments amounted to 21,063 tons and the smelter treated 22,820 tons.

The 264,581 tons of copper-gold ore (dry weight) shipped from the Granby mines during the first three months of 1908, more than doubled the output for the same quarter of 1907, when the tonnage was only 130,483 tons.

The following comparative table shows the output for both quarters segregated:—

	1907.	1908.
January	34,192	74,203
February	32,465	80,155
March	63,826	110,223
Total	130,483	264,581

The Granby output practically represents the ore production of the Boundary this year, the Snowshoe, Crescent and Sally being the only other shippers. The Granby freight and treatment rate has now been got down to the $2.50 mark. On the tenth instant at Phoenix the Granby employees received $55,000 for their March wages, and at the smelter $35,000 was distributed. Hereafter 15,000 tons of ore will be kept on hand at the smelter as an emergency lot.

A small gasoline prospecting plant has been set up at the Little Bertha and some development work will be done. The Crescent mine has closed down. The plan of operation is to be modified. Mrs. Ida M. Parsons, of Minneapolis, secretary of the Alliance Gold & Copper Mining Company, is in Greenwood on business for that company. This company owns the Moreen, electrically equipped, claim, in Deadwood camp. Word has been received that the men

who are promoting the Greenwood prospecting tunnel idea in Chicago have succeeded in raising funds to begin the work.

SLOCAN, ETC.

The Blue Bell, on Kootenay Lake, which supplied the early trappers with lead for their bullets, is to be worked on a larger scale than heretofore, this season. There are big ledges of lead and zinc on this property. A syndicate of London and Nelson men have secured a lease on the Hall mine, near Nelson, and will begin work at an early moment. As to whether they operate the smelter or not, that will depend upon how the work at the mine turns out. A New York syndicate has purchased the Molly Gibson group of claims in the group. Assays made from the ledge average from $10 to $80 and $100. The Slocan Star Company has encountered a good ore body on the Hidden Treasure. A Nelson syndicate has bought the moiety of a Spokane man in the Nugget on Sheep Creek. A company has been organized to take over the Ophir-Lade, Lucky Jack and Swede groups of the Great Northern Mining Company, and development work is to be started. The Silver Cup mine has a good reserve of ore blocked out and the mine is looking well. The 160 tons of ore shipped in March netted the company $10,000. A rich strike has been reported from the St. Elmo claim of the True Fissure Company. Shipments are being made to Trail smelter. The ore runs as high as $80 per ton.

A strike of good ore has been reported from the Half Moon prospect at Moyie, near the St. Eupene. Development on the Aurora, across the lake from the St. Eugene, is giving good results. A quantity of shipping ore is blocked out. The St. Eugene paid out $40,000 wages for March.

The Big Bend Mica Company has been organized to work 1,400 acres of ground north of Revelstoke. The Tyee Copper Company has taken a bond on a rich group of claims on Moresby Island. Great activity will be manifested on the Queen Charlotte Islands in the future. There are many rich mines there that can be worked with copper at a very low price. Some of the ore now being mined runs from $60 to $100 per ton.

The following shipments were made through Kaslo during March:—

	Tons.
Whitewater, concentrate	266½
Whitewater Deep, concentrate	22½
Rambler	179
Ruth, concentrate	40
Reco	20
Slocan Sovereign	20
Ferguson Mines (sampler)	60
Total	548

The Sullivan smelter will continue to be operated until the supply of ore on hand is treated.

The International Coal & Coke Company have declared a 2 per cent. dividend, payable May 1st. They are shipping 2,500 tons of coal per day and are making preparations to increase their output to 3,000 tons. Diamond drill prospecting is being done on the Royal Collieries ground.

Negotiations are now pending for the sale of the only known large hematite iron ore deposit on the coast. This deposit is on Salt Spring Island, and Seattle people are endeavoring to acquire it.

As the gneiss and schist formation in the Findlay river country is favorable and as there are numerous streams to assist in collecting the precious metal, it is stated that there is no reason why there should not be plenty of gold in that district. It is the consensus of best opinion that the most favorable route to these "diggin's" is via Port Essington and Hazelton.

GENERAL MINING NEWS

NOVA SCOTIA.

HALIFAX.—The following bill was introduced by the Commissioner of Mines on Tuesday, April 7th. It is supported by the Dominion Coal and the Nova Scotia Steel Companies, and is opposed by the Dominion Steel Company:—

The bill was read a second time Wednesday and sent to the Law Amendments Committee, before which the struggle is now being conducted.

The text of the bill is:

Be it enacted by the Governor, Council and Assembly as follows:

1. Notwithstanding any provision of "The Mines Act" or any amendment thereto, the Governor-in-Council may, on application of any person interested, cause to be made a re-adjustment and settlement of the boundaries of any lease or leases of submarine coal mining areas situated in the County of Cape Breton or elsewhere in the discretion of the Governor-in-Council, and may if necessary change the boundaries of the area or areas covered by said lease or leases.

2. If it should appear that, by reason of some error or inaccuracy in the description of the boundaries of any lease or leases, areas which were intended by the applicant to be adjoining areas and are shown as adjoining areas on the official plan on file at the Mines Office, do not actually adjoin, but are separated by an area or areas, tract of ground or territory not actually covered by said descriptions, the Governor-in-Council shall have power to extend the boundaries of such lease or leases so as to include such area or areas not covered by said descriptions, notwithstanding that any such lease may thereby include more than one square mile, and notwithstanding that application may have been made for a license to search or lease such areas or areas not covered by said descriptions or any part thereof.

3. Before any such re-adjustment, settlement, change or extension of boundaries is made, such parties interested in the lease or leases affected and any lease or leases, license or licenses to search which may be affected, as the Commissioner directs, shall, at least ten days before the hearing of such application be notified by the applicant of the time and place of the hearing of such application by the Governor-in-Council.

4. The hearing of such application may be adjourned from time to time, and any surveys may be ordered to be made, and for all the purposes of the hearing of any such application, the Governor-in-Council shall have all the powers which the Lieutenant-Governor has power to confer upon a Commissioner under chapter 12 of the Revised Statutes, 1900, "Of Inquiries Concerning Public Matters."

5. Upon the making of any Order in Council under the provisions of this Act the title to the coal in the areas affected by such Order in Council shall vest in the respective lessees whose areas are affected thereby according to the terms of such Order in Council, and the description of said areas as contained in the respective leases may be surrendered and new leases issued in lieu thereof containing the same terms and conditions as the surrendered leases, but containing new descriptions, varied according to the provisions of any such Order in Council. Any lease so changed or new lease so issued shall be valid and effectual for all purposes as if the

same had been issued under the Mines Act and amendments thereto.

6. Unless otherwise ordered by the Governor-in-Council all expenses incurred in connection with the hearing and determination of any such application shall be paid by the applicant.

ONTARIO.

PORT ARTHUR.—The Atikokan Iron Company will soon put the blast furnace in commission again. Orders for pig iron have been placed and only the opening of navigation is awaited.

SAULT STE. MARIE.—On April 9th a notice was posted at the steel plant of the Lake Superior Corporation stating that the works would be closed down until April 13th. Scarcity of pig iron was the cause.

LARDER LAKE.—Mr. Englehart, chairman of the T. & N. O. Railway, was recently presented with a petition requesting the immediate construction of a railroad from Boston station to Larder City. Mr. A. A. Cole, the engineer of the T. & N. O., is to make a preliminary survey of the proposed route at an early date.

COBALT.—The fire at the Foster mine destroyed only a small warehouse, which was fully insured.

During the week ended April 11th the McKinley-Darragh made considerable shipments of low grade ore to the Deloro smelter. Twenty miners are working double shift.

BRITISH COLUMBIA.

FERNIE.—The slack demand for coal has not affected the coke output. The C. N. R. Coal Company's ovens are in full operation.

The Crow's Nest Pass Coal Company is to make extensive improvements in its plants at Coal Creek and Michel collieries. New compressors, haulage system and other machinery have been installed, and the large new steel tipple at Michel is being rushed.

NELSON.—It has been announced that Mr. M. S. Davys, who is now in London, Eng., has succeeded in forming a development syndicate for the purpose of working the Silver King mine. The Hall mines smelter was originally built to treat the Silver King ores.

VANCOUVER.—Gypsum has been discovered in commercial quantity within 60 miles of Vancouver. A plant is to be erected.

Phoenix, April 14.—On Sunday, for the first time in many weeks, practically no work was done at the Granby mines, and for the next two months or more there will be no Sunday work at these properties. Manager Hodges states that this is on account of reducing the shipments somewhat for a time, this in turn being caused by the blowing-out of a furnace for connecting up with the new steel flue dust chamber. Now that the organization is complete and in excellent running order, the management prefers to give the employees a day off every week and not lay off any of the men, those at the smelter being largely absorbed in the new work going on.

To-day the first of the battery of eight blast furnaces was blown out for connecting up, and they will be treated in this way one after another, leaving an average of seven furnaces in blast all the time. When the No. 2 furnace was allowed to go cold to-day, it was the first break in the remarkable run made by the smelter recently—the best in its history. For six or seven weeks the entire battery had been in commission, without a break of a single furnace for as much as 24 hours, which is considered by smelter experts a remarkable achievement in smelter practice with so large a battery of furnaces.

For the months of April and May, at least, the tonnage treatment of the Granby smelter will be, probably, from 15,000 to 20,000 tons less than for the month of March, which far exceeded all previous records at this or any other smelter in Canada.

Part of the structural steel has begun to arrive at the Granby smelter for the extensive enlargement of the converter building, and from this on carloads of material will be brought in from the east for this and other enlargement purposes, which are to begin this summer and give the smelter when completed a daily capacity of 4,500 tons of ore.

ALBERTA.

Calgary, April 16.—Three men were killed and four others seriously burned by an explosion at what is known as the Old Mine at Canmore yesterday. The dead are Gus Capelson and Matt Starr, Finlanders, and W. Wilmott, an Englishman, acting as fire boss. The latter leaves a wife and family of four little ones, who only arrived from England a few months ago. The injured are all Finlanders. The cause of the explosion has not been determined yet, and the mine has been closed, pending an investigation.

Edmonton, Alta., April 16.—An explosion of gas occurred yesterday afternoon at 1.45 o'clock in the Dawdo coal mine on the south bank of the Saskatchewan river, opposite the Alberta Penitentiary, which resulted in two coal miners, Joseph Anderson and Andrew Hugle, being injured. The cause of the explosion is supposed to have been the sudden liberation of some gas which was ignited by the open lights worn by the two men.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The quantity of coal mined in the United Kingdom, which was 251,050,809 long tons in 1906, increase to 267,828,276 long tons in 1907. Of the latter quantity, England furnished 187,383,846 tons; Wales, 40,252,178; Scotland, 40,092,548; and Ireland, 99,704 tons. The number of persons employed in workings coming under the Coal Mines Act was 757,887, an increase of 58,273 over the previous year.

Ten miners were killed in an explosion of coal gas in the Norton Hill colliery, Somersetshire, on April 10th. A rescue party were overcome by the fumes and saved only with the greatest difficulty.

FRANCE.

French imports of nickel from New Caledonia have been about 120,000 tonnes during the last three years. The production of metal at the works of the Societe Le Nickel near Havre is from 1,700 to 1,800 tonnes annually. The company is about to build a plant at Port Bouquet for treatment of ores and refining. After treatment in waterjackets the ore will be transformed into oxide by calcination and then refined for pure nickel. Electric furnaces will also be installed for the manufacture of ferro-nickel.

The French production of ferro-manganese and spiegel in 1907 was 27,000 tonnes.

INDIA.

A discovery of tungsten ore has been made at Agargaon, some 25 miles south of Nagpur in the course of prospecting for manganese. The occurrence of the ore which is found in quartz stringers in a belt of mica schist has been proved for a length of 1,400 feet.

A special survey of the tin mining industry in South Burma is being undertaking by the Indian Geological survey. The industry has expanded considerably during the last two years, the output of tin ore from the Mergui and Tavoy districts having advanced to a value of £13,574 in 1906-7.

NORWAY.

The Norwegian Government has appointed an official commission to make an investigation into the actual condition of the manufacture of pig iron and steel in Europe by the electric process.

ITALY.

A 15,000 horse-power hydro-electric works has been built on the River Pescara, at Piano d'Orte for the manuracture of cyanamide by the process invented for the fixation of atmospheric nitrogen.

GERMANY.

The zinc ore production of Prussia in 1906 was 702,932 tons of which 188,249 tons cisonsted of calamine and the remainder of blende. The number of workmen employed was 16,366.

RUSSIA.

Gold mining in the Amur region is undergoing a serious crisis the yield of gold having fallen from 642 poods in 1901 to 470 poods in 1905 and preliminary estimates for the last two years placing the yield at about the same figure as that of 1905. Increased cost of labor and unsettled conditions are assigned as the cause.

The year 1907 witnessed a great development in the manganese ore industry of the Nikopolsk region, South Russia. There were 15,500,000 poods extracted and 16,320,000 marketed in that year as compared with 9,580,000 poods extracted and 12,650,000 marketed in 1906.

SOUTH AFRICA.

The experiment of giving work in the Rand mines to the unemployed has proved a failure. It was proposed to take on 400 men for unskilled labor, some of the mines offering 4 and others 3 shillings per day but the men generally declined to accept these terms.

The working costs of the Robinson mine, Johannesburg during March amounted to 13 shillings per ton which is a record figure.

BRITISH GUIANA.

Gold mining in this colony has been declining steadily since 1900. In that year the output for the fiscal year ending June 30th, was 114,102 ounces and the number of miners employed 16,588. In 1906-7 the output had fallen to 85,505 crude ounces and the number of miners to 8,234.

UNITED STATES.

An agreement was effected at Toledo, Ohio on the 17the of April between representatives of 200,000 bituminous coal miners who recently went out on strike and the operators, under which work in the central districts affected was resumed. The old rate of 90 cents per ton was agreed upon, and a referendum vote on the two-years agreement is to be taken. The working day was fixed at 8 hours.

The Great Bonanza Gold Mining Company of London, England, has bought the Next President and Bledsoe mines near Denver, Colorado, for $40,000.

The American Society of Civil Engineers will hold their annual convention in Denver, June 23—26.

The total value of the metallic production of Colorado in 1907 was $40,847,835, a decrease of $3,051,240 as compared with 1906.

COMPANY REPORTS.

The seventh annual general meeting of the shareholders of the Le Roi No. 2, Limited, was held in London, Eng., on March 3rd, Lord Earnest Hamilton (chairman) presiding. The chairman, in his report, said that the small results of the past year's work do not in any way reflect upon the intrinsic value of the company's property. Advantage was taken, he stated, of the coal and smelter troubles, which restricted the output, to push development in the mine on a more extensive scale than in previous years, and the result has been strikingly successful—so much so that against the poor returns of the past financial year there is a more distinctly favorable outlook with regard to the future than it has been possible to record at any previous meeting.

In regard to the life of the mine, the chairman stated that Messrs. Hill and Stewart, who four years ago declined to guarantee more than eighteen months' life, wive it as their opinion that the company can now look forward to three years of production at the rate of from 2,000 to 2,500 tons a month. The probable reason for Messrs. Hill & Stewart extending the lifetime of the mine to three years is the H Vein, which for a long period on the 500 foot level had been the chief source of supply, has, during the past twelve months, been definitely located on the 700 and 900 foot levels; on both of which levels payable values occur. The diamond drill has also located a payable ore body of considerable size at a depth of 1,350 feet, or 450 feet below the bottom of the shaft. With regard to the immediate future, the chairman stated that there is reason to believe that the company can look forward with tolerable certainty to a succession of good returns from the mine, though it must not be lost sight of that the returns for January were abnormally high and must not be looked on as a sample of what can be expected every month. Still, with returns considerably lower than this, dividends of a satisfactory character can be paid.

In the case of the Coneurry Syndicate, the chairman stated that a profit is at the present moment actually secured.

Chairman Hamilton told the meeting of the success that the company was making of the Vancouver property, in the Slocan, which had developed most favorably during the past eighteen months. The Vancouver mine was one of exceptional value. He stated that it was proposed, with as little delay as possible, to float the Vancouver as a separate company. In this case the Le Roi Two will be in the position of the company promoter and all

the advantages attached to the deal will be offered in the first place to the shareholders of this country.

The chairman paid a high tribute to Paul S. Couldrey, the representative of Messrs. Hill & Stewart at the mines of the company, and said it was almost entirely due to his personal enterprise, energy, ability and devotion to his work that they are in such prosperous condition. He asked Mr. Couldrey to give some information in regard to the company's mines.

Paul S. Couldrey said: With regard to the Josie mine, you will be pleased to learn that we are now working the Hamilton vein on four levels, namely, the 300, 500 and 700 foot, and intermittently on the 900 foot level. I do not think working has ever been so distributed throughout the various levels of the mine as at the present time, certainly not in connection with any one vein. We have now nine or ten stopes working on the Hamilton vein alone, of which the West H stope on the 500 foot level is at the present time about 500 feet long itself. We feel that, having now opened up at so many points and over such a large area, the most regular vein we are ever likely to find in our Rossland properties, the chances of sudden and simultaneous impoverishment everywhere are getting smaller every day. With regard to the ore reserves, we would now have no difficulty in estimating with tolerable exactness the quantity of ore which lies ahead of us in certain specified blocks of ground, but any such estimate would be totally inadequate if they conveyed to you the idea that this was all the ore the mine contained. In opening up the Hamilton vein we pushed the work on the 500 foot level (having ore to follow) so far ahead of all the other levels that it is only now that we are getting to points vertically above and below the eastern end of our West H 500 stope. Hence the impossibility as yet of estimating the ore which lies above or below the 500 West H. without which any estimate would be altogether valueless.

Mr. Couldrey gave considerable attention to the Vancouver mine and stated that concentrates and ore to the value of $100,000 had been shipped in eighteen months. The development work and its good results were reviewed at length, and revealed that the mine is in a favorable condition.

C. Bartlett wished to know how it was that the shipments had not been increased when the prices were high, and now that they had gone down they were increasing their shipments.

The chairman, in reply, said they were more or less in the hands of the smelters, and it did not suit the smelters to take more than a certain quantity of their ore at the then price of copper.

Mr. Bartlett pointed out that the shareholders had not received any pecuniary benefit by the increased cost of copper. That was a most extraordinary state of things.

Mr. Couldrey stated that none of the neighboring companies had reaped any benefit from the increased cost of copper, for the simple reason that when copper went up wages went up, and the Amalgamated Copper Company could afford to pay these wages better than this company could, and they and other powerful companies immediately raised them. After a great deal of heart searching this company raised the wages to $4 a day. Almost immediately after that the copper slump occurred.

Mr. Lionel Harris thought last year's working had been most satisfactory. They had heard with great satisfaction from Mr. Couldrey, and also the chairman, that although they could not look forward to returns, such as they had last January, they might continue to look forward to very satisfactory returns.

The retiring director, Lord Ernest Hamilton, was re-elected.

The chairman stated that the Vancouver was to be incorporated. The capital stock of the company would be £100,000 in £1 shares, divided into 30,000 preference shares and 70,000 ordinary shares. The 30,000 preference shares would be the working capital, which would be offered for subscription. Those who subscribed for these 30,000 preference shares would get as a bonus 20,000 ordinary shares. With regard to the distribution of the profits it was proposed that an annual dividend of 10 per cent. on the whole of the capital of the company would be first paid. This would absorb £10,000. Any surplus profit available for distribution after that 10 per cent. had been paid was to go to the holders of the 30,000 preference shares until they had been paid in full. From that moment the preference shares would cease to exist as preference shares, but they would rank as ordinary shares. It was not intended to take any formal vote on the matter at this meeting. He might add that they proposed to offer these 30,000 preference shares to the shareholders of this company, so that the advantages accruing from this flotation will be divided amongst the shareholders either qua shareholders pure and simple or as members of this company.

On the motion of Mr. Lionel Harris, a cordial vote of thanks was passed to the chairman, directors and staff for the way in which they had conducted the affairs of the company.

SILVER QUEEN

The annual meeting of the Silver Queen Mining Company was held in Toronto on April 22nd.

The Directors Report presented the following facts:—

Receipts during the past year from production or ore amounted to $112,552, and there is still due from the smelters (not including the 22 1-2 tons shipped the other day) $61,860.00, or a total of $174,421.79. General expenses were $90,285.38 leaving a balance on hand and due from smelters, as of March 31st, of approximately $120,000.00.

During the last ten months of the current year the mine produced 20 car loads of ore, three of high grade, four of second grade and thirteen of low grade.

The old officers were re-elected. They are Lieut-Col. John I. Davidson, president; F. L. Culver, first vice-president and general manager; R. W. Gordon, second vice, and J. H. Stephens, secretary-treasurer.

The directors are R. W. Gordon, F. L. Culver, A. J. Young, Lieut-Col. Davidson and P. S. Hairston.

A regular quarterly dividend of 3 per cent. was declared and a bonus of 2 per cent. was added to the first dividend.

SYDNEY CEMENT COMPANY.

The annual report of the Sydney Cement Company, Limited, for the thirteen months ending 31st December, 1907, is extremely encouraging. The total output was 63,498 barrels, more than double the production of the previous year. The sales amounted to 60,496 barrels, as compared with 33,522 during the preceding year.

The net profits show up in a most gratifying way, amounting to $21,416 for the thirteen months, as against $1,468 for the eighteen months preceding.

A dividend of seven per cent. in the preferred stock has been declared, and will, if sanctioned by the shareholders, be paid on June 1st next. In addition to this a total of $13,239.17 was spent during the year in improving and extending the plant.

The installation of a fourth tube will be recommended. This would increase the capacity of the plant by 150 barrels per day, or approximately thirty per cent.

The Sydney Cement Company is the only cement manufacturing plant in Canada east of Montreal. From the geographical position of Sydney, the Company's shipping facilities for the export trade are unexcelled.

The plant has now reached its estimated output. In spite of handicaps, and periods of enforced idleness, the output has steadily increased. When the arrangements have been completed for

doubling the output, costs will have been reduced to such a low figure that the Maritme Provinces' trade can practically be controlled.

"Rampart" cement, the Sydney Cement Company's brand, has won a strong position in the Canadian market. As it is the only slag cement manufactured in Canada, its reputation is of more than passing interest.

Mr. H. C. Burchell, who is Vice-President and Managing Director, has our hearty congratulations, as also have the other executive officers.

STATISTICS AND RETURNS.

The Nova Scotia Steel and Coal Company will send in the vicinity of 270,000 tons to the St. Lawrence this year.

Following are the figures of output for the Dominion Coal Company and the Dominion Steel Company.

The Coal Company's output for the first three months of the year compares as follows with 1907:

	1908 Tons.	1907 Tons
January	314,322	269,090
February	282,508	226,190
March	344,000	212,000
Total	940,830	707,280

The Steel Company is also showing big gains, the output for the three months being:

	1907 Tons	1908 Tons
Coke	91,350	116,500
Pig iron	50,167	79,045
Ingots	54,327	73,764
Blooms and billets	64,664	74,967

The output of the Crow's Nest Pass Coal Company's collieries for the week ending April 17th was 12,908 tons, a daily average of 2,151 tons. All collieries were idle on Good Friday.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:—

	Week end April 11. Ore in lbs.	Since Jan. 1. Ore in lbs.
Kerr Lake	60,330	330,710
La Rose	226,800	1,313,352
McKinley	103,780	942,400
Nipissing	43,260	943,430
Nova Scotia	40,000	120,790
O'Brien	63,810	1,448,190
Temiskaming & H. B.	43,260	361,260

The total shipments for the week were 659,040 pounds, or 329 tons. The total shipments from January 1 to date are 9,574,288 pounds, or 4787 tons.

GRANBY SHIPMENT LIGHTER.

Granby shipments were somewhat smaller for the week ended April 18th, amounting to 22,329 tons. The total for the year to date is 314,625 tons.

ROSSLAND MINE SHIPMENTS.

The shipments from the Rossland mines for the week ended April 18th and year to date are as follows:—

	Week.	Year.
Centre Star	3,136	51,598
Le Roi	1,423	24,435
Le Roi 2	676	10,211
Other mines	.....	500
Total	5,244	86,944

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:—

	April 18. Week end Ore in lbs.	Since Jan. 1 Ore in lbs.
Buffalo	45,200	517,520
Coniagas	.....	380,910
Cobalt Lake	.....	180,610
Cobalt Central	46,880	96,580
City Cobalt	.....	228,080
Drummond	.....	92,340
Foster	.....	168,600
Kerr Lake	.....	330,710
King Edward	.....	127,240
La Rose	123,900	1,437,252
McKinley	60,000	1,002,400
Nipissing	.....	943,430
Nova Scotia	.....	120,790
Nancy Helen	.....	140,420
O'Brien	.....	1,448,190
Right of Way	.....	60,210
Provincial	.....	143,210
Standard	.....	39,730
Silver Queen	.....	480,200
Silver Cliff	.....	52,00
Silver Leaf	.....	62,000
Townsite	.....	85,100
Temiskaming & H. B.	.....	539,000
Temiskaming	.....	237,250
Trethewey	.....	487,116
Watts	.....	114,430

The total shipments for the week were 275,980 pounds, or 137 tons. The total shipments from January 1 to date are 9,515,818 pounds, or 4757 tons. The totals shipments for the years 1907 were 28,081,010 pounds, or 14,040 tons, valued at $6,000,000. In 1904 the camp produced 158 tons, valued at $130,217; in 1905, 2144 tons, valued at $1,473,196 in 1906, 5129 tons, valued at $3,900,000.

BRITISH COLUMBIA SHIPMENTS.

Following are the shipments for the week ended April 11th and year to date:—

Boundary shipments—

Mine.	Week.	Year.
Granby	21,063	292,496
Other mines	.....	462
Total	21,063	292,958
Rossland shipments—		
Centre Star	3,513	49,662
Le Roi	1,193	23,003
Le Roi 2	835	9,535
Other mines	.....	500
Total	5,531	81,700
Slocan-Kootenay shipments—		
St. Eugene	563	7,654
Whitewater	43	401
Whitewater, milled	280	4,060
Poorman, milled	250	2,850
Second Relief, milled	145	1,230
North Star	71	929
Richmond	22	490
Rambler-Cariboo	66	413
Nugget	11	317
Kootenay Belle, milled	25	200
Eva	23	159
Silver Cup	3	115
True Fissure	32	32
Sierro Verde	9	9
Other mines	.....	12,328
Total	1,733	33,634

The total shipments for the past week were 28,327 and for the year to date 408,292 tons.

GRANBY SHIPMENTS.

Exactly 264,581 tons of ore, dry weight, were shipped from the Granby mines during the first three months of 1908, which is more than double the output for the corresponding quarter in 1907, when the figures were 130,483 tons. The March run at the smelter was also phenomenal, the entire battery of eight blast furnaces being operated almost every hour in the 24 for every one of the 31 days in the month. The shipments for March totalled 110,223 tons, the smelter tonnage treated being slightly smaller as a reserve of ore was accumulated at the smelter for cases of emergency.

For the purposes of comparison, the following table will show the output of the Granby mines for each month of the first quarter in 1907 and also in 1908 in tons:

	1908.	1908.
January	34,192	74,203
February	32,465	80,155
March	63,826	110,223
Totals	130,483	264,581

For 1908 the above figures practically represent the output of the entire Boundary, as the only other shipments made from the Boundary since January 1 from any other mines were but a few hundred tons. April will doubtless show a smaller output for the Granby owing to the necessity of blowing out each of the blast furnaces while being connected with the new steel flue dust chamber now about finished and ready for use.

SMELTER RECEIPTS.

	Week.	Year.
Granby	21,063	292,496
Consolidated Company	6,150	77,446
Le Roi	1,241	24,514

The total receipts at the various smelters for the past week were 28,454 tons and for the year to date 400,186 tons.

The production of gold in the Transvaal during March was the greatest for any month, with the exception of last December, according to the face of the figures; in reality, last month's output of 574,902 ounces is better than the December total of 583,526 ounces, inasmuch as the later figure included quite a percentage of reserves that were added to the clean-up of the year. The value of the Rand's yield for 1908 should approximate $160,000,000. In face of more or less serious labor troubles the South African output has almost steadily increased ever since the discovery of the Witwatersrand less than a quarter of a century ago, and the reef has not by any means been exhausted. Science every year brings new ore bodies within reach of the shovel, especially at great depths, while, of course, the cyanide process has enabled the extraction of a much greater percentage of the metal from the ores.

According to L. Vogelstein & Company the figures of German consumption of foreign copper for the months of January and February, 1908, stand thus:—

	Tons.
Imports	29,817
Exports	1,413
Consumption	28,404

as compared with consumption during the same period in 1907 of 16,044 tons. Of the above quantity 21,910 tons were imported from the United States.

WORLD'S COPPER PRODUCTION.

Messrs. Henry R. Merton & Company, Limited, London, has just issued some valuable statistics showing the production of copper.

The 1907 production is figured at 716,435 tons, against 714,100 tons in 1906 and 682,125 tons in 1905.

The principal producing countries are figured to have turned out copper in the past four years as follows:—

	1907.	1906.	1905.	1904.
United States	395,090	409,650	389,120	365,050
Spain and Portugal	49,675	59,320	44,810	47,095
Mexico	56,565	60,625	64,140	50,945
Chili	26,685	25,745	29,165	30,110
Canada	25,615	25,460	20,535	19,185
Japan	48,935	42,740	35,910	34,850
Germany	20,490	20,340	22,160	21,045
Australia	41,250	36,250	33,940	34,160
Miscellaneous	52,130	42,720	42,045	41,560
Total	716,435	714,100	682,125	644,000

The world's production for a number of years compares as follows:—

1907	716,435
1906	714,100
1905	682,125
1904	644,000
1903	574,775
1902	541,295
1901	516,628
1900	489,514
1899	472,244
1898	429,626
1897	399,730
1896	273,363
1895	334,565
1894	324,505
1893	303,530
1892	310,472
1891	279,391
1890	269,455

Market Reports.

Coke.

April 21st—Connellsville Coke, f.o.b. ovens—

Furnace coke, prompt, $1.60 to $1.70.
Foundry coke, prompt, $2.15 to $2.25.

Pig Iron.

April 21st—Pittsburg—

No 2 foundry, $16.15 to $16.55.
Bessemer, $17.50 to $17.90.
Basic, $16.30 to $16.40.
Malleable, $16.90 to $17.15.
Southern, No. 2, $16.90 to $17.40.

Other Metals.

Tin, Straits, 31.90 cents.
Copper, prime lake, 12.90 to 13 cents.
Lake, arsenical brands, 12.85 to 12.95 cents.
Electrolytic copper, 12.875 cents.
Sheet copper, 17 cents.
Copper wire, 14.75 cents.
Lead, 4 to 4.05 cents.
Spelter, 4.675 cents.
Sheet zinc, 7.5 cents.
Antimony, Cookson's, 8.87 to 9 cents.
Aluminum, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $23.50 to $26 per ounce.
Bismuth, $1.75 per pound.
Quicksilver, $45 per 75 pound flask.

April 14	54 3-4	25 1-4
April 15	55	25 3-8

There is little prospect of reduction in Lake Superior ore prices. Hence a number of blast furnaces may be blown out presently.

The copper market is still dull. The belief is current that heavy purchases will soon bring up the price.

SAFETY MEASURES.

In addition to what were previously considered as safety precautions, the Fairmont Coal Company is attacking the three known enemies, powder, gas and dust, in every manner posible, some of which may be of interest here.

Powder.—Ordinary black powder was formerly used in all mines of the Fairmont Coal Company, and it was considered practically safe so long as it was not accumulated in large quantities and not used where gas was generated. Its advantages were that it could be readily secured in any amount at economical cost and that it produced coal of better quality than any other known explosive. These advantages have been sacrificed and black powder is being removed, as a safety measure, as rapidly as flameless powder can be procured in sufficient and regular quantities. The largest mines have already been put on a flameless powder basis with regular shot firers, and the practice is rapidly being extended to the other mines, until black powder will be entirely eliminated. The advantage of the flameless type of powder is that it will not ignite gas or dust, even with a wild or blown-out shot. This feature is, of course, assumed from the numerous demonstrations and past practice. While flameless powder cannot be called safety powder, it certainly does eliminate to a great extent the dangers that accompany the use of black powder.

Firedamp.—Gas has ever been the greatest enemy of the mines. Its properties in the simple state are thoroughly known and the danger of its presence appreciated. The common methods of its detection depend considerably on personal opinion and fail entirely on low percentages. Mine air in which no gas can be detected by the ordinary safety lamp, is considered safe for all practical purposes. This would certainly be the case if only gas was to be contended with, but complicated with the two other dangers, powder and dust, this decision loses its positiveness and becomes a matter of degrees. Literature does not enlighten us on how much firedamp is allowable in the return air course or the return of a split. Whatever the general opinion may be it certainly should be less than could be detected by a safety lamp of the Wolf pattern.

While none of the mines of the Fairmont Coal Company are considered gasey, in the opinion of the State Mine Inspector, yet for additional security it was decided to put on a gas inspector to report on such of the mines as have shown an accumulation of firedamp. This inspector is provided with, in addition to the Wolf safety lamp, an aneroid barometer, anemometer, water gauge, wet and dry bulb thermometer and sample can for taking mine air samples. The anemometer measurements are for the purpose of checking up the mine foreman's reports on ventilation and also to estimate the quantity of water carried by the air in connection with the humidity as determined by the hygrometer.

The mine air samples are taken to the laboratory, where the CO_2 and CH_4 are determined. The method used can be relied upon to one-hundredth of 1 per cent. It has been found that one inspector can cover five mines a week, do all the analytical work and make his report.

Branches at COBALT and LATCHFORD, in the silver mining camp of New Ontario.

Easy to Lay

THE first ready roofings, made some thirty years ago, lasted a very short time.

Then manufacturers improved the goods and smooth surfaced roofings of various kinds were developed that would endure fairly well *if the top surface was given a coat of heavy waterproof paint every two years.*

Now comes Amatite—with a mineral surface which requires no painting and which will last longer *without painting* than the other kind did *with constant painting.*

The top surface, being mineral is unaffected by weather or climate.

It really protects.

The waterproofing material in Amatite is pitch—*the best resistant to water known.* Water will in time dissolve or disintegrate almost anything, but it is powerless against pitch.

Roofings of twice the price often do not protect as well because they are not waterproofed with pitch.

Amatite is easy to lay—any one can do the work. We furnish you free nails and liquid cement for laps.

Investigate the cost of Amatite in your locality. You will be astonished at its low price.

MINERALS
And How They Occur

A Book for Secondary Schools and Prospectors

BY

WILLET G. MILLER

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, now in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How They Occur" can be obtained from the Canadian Mining Journal

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

The Latest Book on the Electric Furnace

Electric Smelting is a subject of increasing importance to Canadian Engineers and this work contains a clear and connected account of the principle on which electric furnaces are constructed, the uses to which they can be put and the more important details of their construction. The articles upon which the book is based appeared in the Canadian Engineer during 1906.

The Electric Furnace

Its Evolution, Theory and Practice

By Alfred Stansfield, D. Sc., A.R.S.M.

Professor of Metallurgy, McGill University

208 Pages. Fully Illustrated. Price $2.00.

The evolution of the Electric Furnace from its simplest beginning is as briefly set forth as is consistent with clearness, together with the important facts relaring to its theory and practice.

The rapid growth of the Electric Furnace makes it increasingly difficult for the metallurgist to keep in touch with its recent developments. A few years ago it was a scientific curiosity, but now it threatens to rival the Bessemer converter, the open-hearth steel furnace, and even the blast furnace itself.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work, by reason of their high air efficiency, substantial design, and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)

SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines, in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.

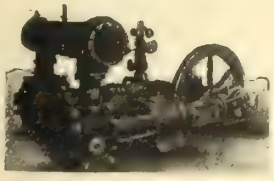
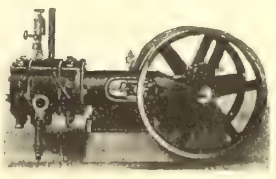
ECLIPSE ROOFING



Waterproof and Odorless—
Reliable — Durable — Adapted
for Steep or Flat Roofs.
Ready for use when shipped.
No Coating or Sanding.
Easily and Quickly Laid—
Elastic—Pliable—Fire Resisting



The foundation or base of Eclipse Roofing consists of a Wool Felt especially made for this purpose. After thorough testing it is treated with a special mineral-caoutchouc compound having a high melting point—220° Fahrenheit—and is coated by a hot process with a special powdered asbestic lubricant. It contains no coal tar and imparts no taste or odor to water. Steam, acids, gases or condensation do not change it. Remains unaffected by the water for years.

THE DATA OF GEOCHEMISTRY.

T. Sterry Hunt, whose monumental labors on the chemistry of geologic phenomena were the foundation of modern geochemistry, was a daring and brilliant adventurer in the realms of science. Posepny's monographs changed the current of geological thought in the last decade of the nineteenth century. The able and tireless Van Heiss added the fruit of his careful work early in this century. Meanwhile geologists, chemists and mineralogists on this continent and in Europe have published the results of special research in official bulletins, scientific periodicals, or in other forms.

Thus a vast bulk of geochemical data has appeared in papers, magazines, and pamphlets, over a considerable period of time. It is not incorrect, however, to state that since 1900 a far greater amount of accurate work has been reported than in any preceding corresponding period.

So important are many of the recent contributions to our knowledge of geochemistry, and so easy is it for excellent work to be crowded out of the field of our attention, that we are impelled to make prompt acknowledgment of the value of a monagraph just published by the United States Geological Survey. Under the title "The Data of Geochemistry," Dr. F. W. Clarke has gathered and correlated an astonishing amount of well-sifted, sound, information.

No mere compiler could have attempted this work. No mere academician could have made it a coherent whole. Dr. Clarke has drawn upon every available source. His foot-notes constitute in themselves a copious bibliography. The scope of the monograph is splendidly wide. Its details are full and accurate.

The sequence of subjects treated in Dr. Clarke's monograph is, roughly, this:

The Nature and Distribution of the Elements.
The Atmosphere.
Lakes and Rivers.
The Ocean.
Waters of Closed Basins.
Mineral Wells and Springs.
Voncanic Gases and Sublimates.
The Molten Magma.
Rock-forming Minerals.
Igneous Rocks.
Decomposition of Rocks.
Sedimentary and Detrital Rocks.
Metamorphic Rocks.
Metallic Ores.

The Natural Hydrocarbons.
Coal.

In that the volume before us has made existing data available to the reader, it has fully justified its preparation. More than this, whilst its author expressly disclaims any attempt at presenting an exhaustive monograph upon geochemistry, he has done something much more desirable. He has given us a readable book that is at once a complete work of reference, and a sufficient resume of the best modern thought upon a subject that hitherto has been beset with discouraging difficulties.

ST. LAWRENCE COAL TRADE.

Late in April five of the Dominion Coal Company's fleet of colliers suffered delay in Quebec harbor. Coal would have been delivered at Quebec to supply the local market had the Louise Basin not been blocked with ice. The local authorities apparently made no attempt to facilitate matters for the large colliers, although it is obviously their duty to aid in every possibe way.

The Dominion Coal Company is making an earnest attempt to take advantage of the early opening of navigation. Throughout the past winter an enormous quantity of coal has been banked at Glace Bay. Sixteen colliers are in their employ, and in the third week of April coal to the amount of 60,000 tons was on its way up the St. Lawrence. It is hoped that 1,300,000 tons will be carried to Montreal before navigation closes. Much depends upon an early start. Last year's shortage should not occur again.

It is quite evident that the Nova Scotian collieries are anxious and willing to rush deliveries. In this they should be assisted.

ROSSLAND.

News from Rossland gives continued hope that mining in the South Belt will develop into a substantial mining camp. Much of the ore so far encountered is rich. The auriferous lead-silver ore, of which light shipments have been made from several prospects, is reported to range from $30 to $70 per ton. Prospectors are actively taking up areas and many properties are being worked on lease.

It were mischievous to speculate as to the results of development. But the facts themselves are sufficiently encouraging.

ZINC.

The opening of the Canada Zinc Company's smelter at Nelson, B.C., will have a doubly beneficial effect upon the Slocan lead mines. Heretofore the lead smelters have penalized the zinc contents of ore. Now the zinc ores of the district will be provided with a ready market and zinc contents of the lead ores will no longer be considered detrimental.

COBALT—PRESENT AND FUTURE.

A year ago the atmosphere of Cobalt was filled with the fever (and ague) of perilous promotions. To-day Cobalt is a strenuous mining camp, working out its own salvation with quiet confidence.

By the great majority of those directly interested in Cobalt a boom in stocks is not desired. The recent brisk movements, excited by several spectacular discoveries, may or may not assume boom dimensions. If they do, then Cobalt will have another load added to a sufficiently sizable burden of capitalization. We sincerely hope that neither by manipulation nor by the ungoverned enthusiasm of a gambling public, Cobalt stocks will move heavenward. They are now resting on much solider ground than ever before. Artificial inflation means catastrophic collapse.

Public attention has been caught and held by recent rich discoveries. These are phenomena that will probably recur from time to time. There are and always will be persons anxious to take advantage of the excitement of the moment to unload worthless paper. The Canadian public should need no warning. But there is another aspect of Cobalt. A few weeks ago a meeting of the Cobalt Branch of the Canadian Mining Institute was held. About fifty mine managers, engineers, mill men and other practical workers attended and took part in the proceedings. The object of the meeting was to discuss concentration methods. In itself this is a significant fact. It marks the strongly progressive tone of the camp. Superintendents, who not many months ago were in charge of one or two holes in the ground, must now attack the knotty questions of ore-dressing. Amongst these operators the most general topics of conversation are not the merits of stocks, but the comparative efficiency of different makes of air drills, crushers, rolls, concentrating tables and all matters pertaining to the mining and treatment of ore.

The skill and care of the mine managers of Cobalt have imparted real value to shares in many of the older companies. The list of shipping mines is constantly being added to, and Cobalt is giving us performance in place of promise.

The future of Cobalt lies largely in the hands of technical men. The camp is assured a fair lifetime, even from present developments. But the intelligent application of technical experience in the selection of suitable mining and concentrating equipment, and in the economical generation of power, will prolong indefinitely the productive future of the district.

It is imperative that mine managers should keep thoroughly informed concerning improvements and changes in methods and machinery. The insufficiently posted manager is painfully apt to develop costly fads. To a few, complicated machinery appeals because it is complicated. Often the personal predilections of a member of the directorate carry more weight than the

recommendations of the superintendent. But the competent manager, upon whose shoulders falls the whole responsibility of failure, must be allowed to choose his own supplies, both of men and machinery.

One feature of life in Cobalt that obtrudes itself unpleasantly upon the visitor is the prevalence of the "blind pig." A moderate estimate places the number of these illicit liquor shops at thirty-five. In open defiance of the law the vilest liquor is sold day and night. As a consequence the proprietor of the "blind pig" usually a "fence" for the "high grader."

There may be difference of opinion as to extent to which "high grading" obtains in Cobalt. Those who have studied the question claim that large amounts of silver are daily disposed of. Whether the total is large or small is not our present theme; but it is certain that "high grading" would be practically eliminated if the "blind pig" did not exist.

The onus of these conditions cannt be thrust upon the Government. It behooves the citizens of Cobalt to do a little house-cleaning.

No reference to mining in Cobalt would be complete without mention of the excellent topographical and geographical map issued and distributed by the Ontario Bureau of Mines. It was compiled by Dr. W. G. Miller and Mr. C. W. Knight, and it has afforded untold help in development and prospecting.

MINING FLOTATIONS AND THE PRESS.

The general report of the Grand Jury, which last December returned a true bill against Frank Law, refers in the following terms to the newspaper practice of printing any and all mining advertisements that are offered:

"We have heard sufficient evidence to convince us that the public have been swindled out of large sums of money in the flotation of mining companies. The prospectuses issued by many of these companies are not only intentionally misleading, but oftentimes false and fraudulent in the statements contained in them. The mining industry is destined to assume large proportions in Canada and in Ontario, and it is very much in the public interest, as well as in the interest of private individuals, that it should be conducted honestly and in such a way as to inspire confidence at home and abroad.

"The flotation of wild-cat propositions depends largely for their success on advertising in the daily press, and it is a regrettable fact that the newspapers do not caution the public in regard to ventures many of which are illusory and fraudulent on their very face. If the newspapers cannot be held responsible for aiding and abetting this kind of fraud, the Government should at least see to it that the laws are made wide enough to include fraud of all kinds perpetrated by the officers of the companies, and the brokers concerned, and furthermore that such laws are rigorously enforced."

SUMMER EXCURSION OF THE CANADIAN MINING INSTITUTE.

Plans for the visit of representatives of British technical and scientific societies are being perfected. Delegates have been invited from the Iron and Steel Institute, the Institute of Mining and Metallurgy, the North of England Institute, the South Wales Institute of Engineers, the Institute of Scotland, and the Manchester Geological Society.

Already a number of these representatives have signified their intention of coming over to Canada in August. Fifty provisional acceptances have been received by the secretary of the Canadian Mining Institute.

The proposed itinerary of the trip is printed on another page of this issue. It is, of course, open to change and has been suggested merely as a working basis. Indeed, the itinerary is now printed in the hope that those interested will give their opinions as to necessary modifications.

THE FRANK LAW CASE.

Anxious enquiries have reached us at divers times regard the progress of the case of Rex. vs. Frank Law. Rumors have been circulated that the case has been settled or dropped. These are utterly unfounded. County Crown Attorney Drayton consented to traversing the case until the June Sessions in the hope that Russell, Law's partner, would be extradited before that time.

The case is now "sub judice" and comment is out of order. The public may rest assured, however, that proceedings have not been and will not be dropped.

The finding of the Grand Jury reads thus: "That Frank Law, at the City of Toronto, in the County of York, in the year of our Lord one thousand nine hundred and seven, did unlawfully, fraudulently, and deceitfully combine, conspire, confederate, and agree with William Lockard Russell and with other persons to your jurors unknown to defraud the public market price of price and shares publicly sold, and did thereby commit an indictable offence, contrary to the provisions of the Criminal Code."

Contributors who send us photographs will do well to remember that a dull finish is difficult to reproduce. Good half-tones can only be secured from a "burnished" photo.

MINERAL LOCATIONS ON MORESBY ISLAND—ONE OF THE QUEEN CHARLOTTE ISLANDS.

(Abstract of Bulletin No. 1, issued by the British Columbia Bureau of Mines.)

The Queen Charlotte group of islands lies between the 52 and 54th degrees of north latitude and about 85 miles westward of the mainland, at the mouth of the Skeena river. The distance from these islands to the nearest of those islands lying adjacent to the coast of the mainland is from 60 to 70 miles across an open stretch of water—Hecate straits—sufficiently open to the Pacific ocean to share its waves and winds. This has proved enough of a barrier to prevent much intercourse by small boats between these islands and the mainland, while, until within the past year, communication by steamer was only to be had once a month. These islands, so commandingly situated off the main coast, have therefore remained sufficiently terra incognita to stimulate the imagination and create much interest.

The outline of the west coast of the islands, as shown on the Admiralty charts, is from a rough survey made by Vancouver in 1793, while cruising along the coast in a sailing ship. The east coast line is a little more accurately marked, as this was investigated in 1878 by the late Dr. G. M. Dawson, of the Geological Survey, who made a rough reconnaisance survey, the comparative accuracy of which, though a tribute to that wonderful explorer, still leaves much to be desired.

Historical.

The early voyages of discovery to the vicinity of the Queen Charlotte Islands, and in fact the entire northern Pacific coast, were all in search of a supposed northern passage for vessels from the Atlantic to the Pacific Ocean—in other words, a short waterway from Europe to China.

As early as 1592 the Spanish Viceroy of Mexico fitted out an expedition for this purpose under Juan de Fuca, who sailed as far north as Vancouver Island, although it is not known that he ever reached the Queen Charlotte Islands.

In 1639 the Court of Spain appointed Bartholemew de Fonte to command a squadron, fitted out in Peru, which sailed in 1640. In June, 1640, he records entering an archipelago of very many islands, called by him St. Lazrarus, in latitude N.53 degrees—the latitude of the centre of the Queen Charlotte group — and that he sailed for many leagues through intricate channels between islands. These may have been the Queen Charlotte Islands, but some doubt has been entertained as to the accuracy of both these early voyagers.

In 1774, Juan Perez, in the Spanish corvette "Santiago," saw and named the north cape of Queen Charlotte Islands Cape de S. Margarita, but, finding no anchorage, did not land.

In 1775, another Spanish expedition, under Bodega and Maurelle, coasted along the shores of the islands, but did not land.

In 1787, Dixon, in the British ship "Queen Charlotte," spent over a month on the coast of the islands, tracing the west coast from the north to the south end and sailing up the east coast as far as Gumshewa Inlet, and named the group of islands after his ship. He traded with the Indians, buying furs, etc., the real object of his voyage.

During the next few years the islands were frequently visited by fur traders in British, French, Spanish and American vessels.

In 1792, Capt. George Vancouver, in H.M.S. "Discovery," arrived on the west coast of America, and during the next three years was engaged in a series of surveys and explorations which to-day form the basis of our present charts of the west coast of these islands.

Attention seems to have been withdrawn from the islands with the abandonment of the search for the "Northwest Passage," until 1852, when H.M.S. "Thetis" visited the islands on a surveying expedition, followed, in 1853, by H.M.S. "Virago," and by H.M.S. "Alert" in 1860.

"In 1852, the Hudson Bay Company despatched a party of men in the brig 'Una,' Captain Mitchell, to discover the locality from which several specimens of gold had been brought by the Indians. This was found to be on Gold Harbor, in Kuper Inlet, on the western coast of Moresby Island. The gold was found in a small irregular vein, which soon proved to 'run out' in every direction. The quantity of gold obtained by the expedition was considerable, but has been variously stated. The enterprise was soon abandoned, but the discovery for a time created quite a furore—the first gold excitement in British Columbia—and the locality was visited by a number of miners, but with no further success."

As to the amount of gold actually obtained in this first expedition, no very authentic account is obtainable; tradition makes it very large, but Major Downie, mentioned further on, who visited the locality a few years later on a similar errand, places the amount at $5,000.

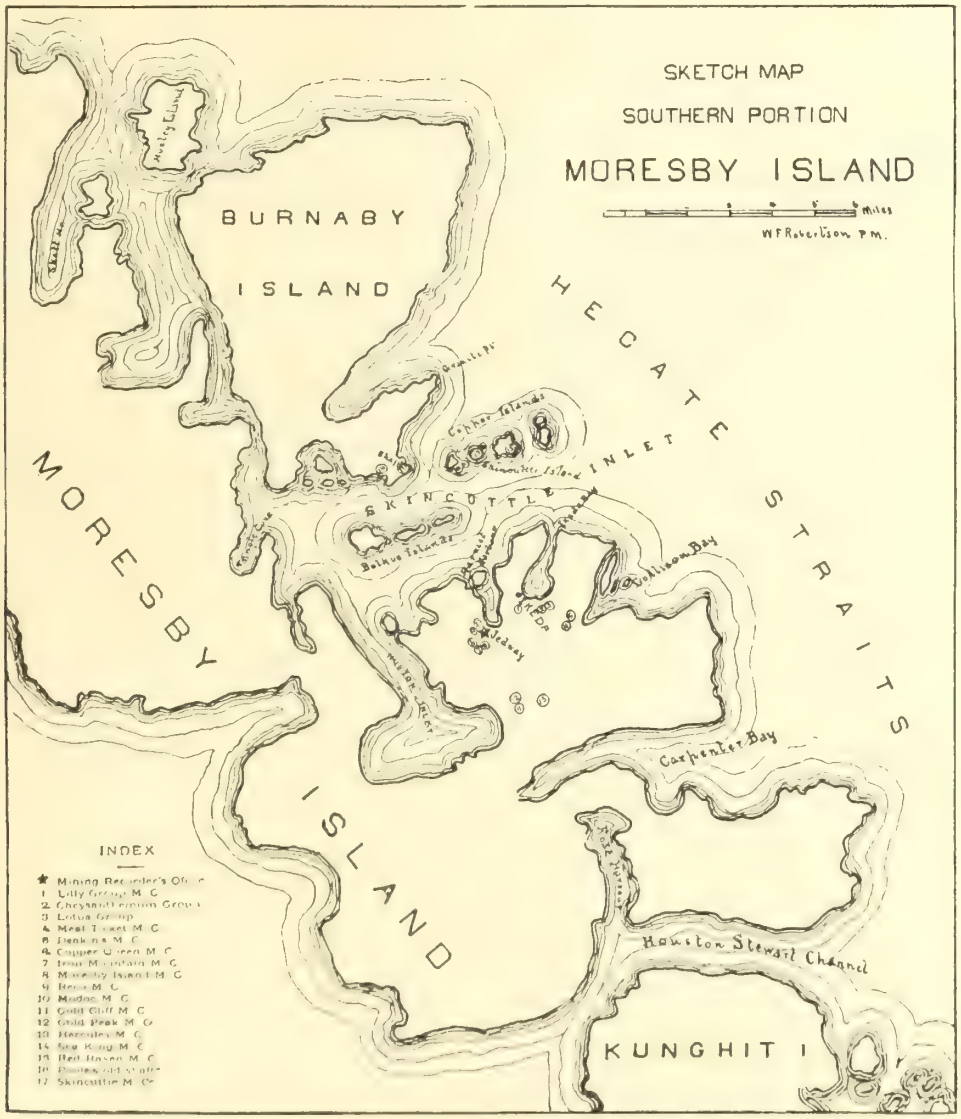
In 1859, Major William Downie, a miner, with a party of 27, in a schooner, under Capt. Robinson, went to Gold Harbor, and he records in his book "Hunting for Gold" that the party found quartz but no amount of gold. They "examined the spot where a large quantity of gold had been taken out some time before, but could not find anything worth working." Major Downie, however, reports that he found coal on Skidegate Inlet, and he is the first to have mentioned its existence on the islands. He, however, did not follow up his discovery, but soon left for the mainland.

In 1862 the "Queen Charlotte Mining Company" was formed in Victoria, and a party of men under Mr. Francis Poole—an Englishment, claiming to be a mining engineer—was sent north, landing on Skincuttle Island in the inlet of that name, on which island and the adjoining island, Burnaby, they remained until 1864, engaged in prospecting. Their prospect shafts, etc., are still visible to-day and have been re-staked by present-day prospectors, more, it seems, on their historic fame than on the amount of mineral visible. Mr. Poole gives an account of his expedition in a book, "Queen Charlotte Islands," published in London in 1872.

As far as is known, this constitutes the sum of the recorded early prospecting ventures on the Queen Charlotte Islands. That there have been some unre-

corded ventures is evidenced by the fact that at Copper Bay, some nine or ten miles south of the Sand Spit, there is the remains of an old shaft, now being unwatered and cleared out, which has been proved to be at least 100 feet deep, and of which there is no record.

Despite the fact that the early prospectors had all found enough to indicate the probability of extensive mineralization on the islands, for many years these discoveries were not followed up and little or no serious prospecting took place. It was only when attention was focussed on this northern part of the coast, by the location therein of the terminus of a transcontinental railway, that the Queen Charlotte Islands again received attention from the prospector, and the more valuable discoveries that have been made have been all located within the last two years, many within the past year. The area found to contain mineral is so extensive that prospectors, having performed sufficient work on their respective claims to hold them for the year, have stopped at that and spent their time in trying to locate further mineral deposits.



As a result, it was found on examination that, with one or two exceptions, there were to be seen only surface prospects, of which no very definite future can be foretold.

As was natural, when prospecting was resumed, it began in the vicinity of the indications found many years ago, and has proceeded along the "line of least resistance," that is, in the direction from the initial point which could most easily and safely be reached by small boats.

Skincuttle Inlet was the starting point, and the majority of the claims so far staked have been in the bays or harbors opening off this inlet, viz., Huston Harbor, Harriet Harbor, Ikeda Bay and Collison Bay, with a few, and, at present, not so important localities farther south.

From Skincuttle Inlet prospecting continued north, and some important locations have been made along the east coast from Klunkwoi Bay to Gumshewa Inlet, in a formation quite different from that found in the vicinity of Skincuttle Inlet. As yet, all the locations have been made close to the sea shore, within distances that could be reached in a day from a boat.

The formation, which has been found copper bearing, at Klunkwoi and Gumshewa Bays, appears to continue N.W., parallel to the length of the island, and is again found on the north end of Moresby Island, an Skidegate Channel, between the Narrows, where also it is impregnated with copper, but whether the metal is here in commercial quantities has not yet been demonstrated.

Climate.

The climate of Moresby Island is particularly favorable to prospecting and to subsequent mining operations, since in summer it is never very warm, while in winter there is seldom snow or frost in the lower lands, although both are to be found on the higher mountains, the highest peaks retaining snow caps well into summer.

The west coast of the island is always dangerous to approach owing to the rocky character of its shores and the prevailing west wind, causing an ever-present ocean swell, which renders landing from a small boat very difficult except in the sheltered bays, and these bays, though quite numerous, are still uncharted and unknown save to a few prospectors, who have bought their knowledge by hard experience.

The east coast is in summer usually safe, as it is protected from the west wind by the main island, and the fringe of smaller islands along its shores affords some protection, and offers ample refuge, from all winds, the inner passage being always navigable for small boats.

The warm winds off the Pacific, striking the high mountainous backbone of the island, produce in winter a great deal of rain and in summer a mist, which, however, seldom develops into fog.

As compared with the shores of Vancouver Island, those of Moresby Island are comparatively free from troublesome underbrush.

The timber, though small for lumbering, is admirable for mining purposes, and is very plentiful, while the damp climate does away with the dangers of forest fires.

There is little soil to hamper prospecting, the surface being, however, heavily carpeted with moss.

Game.

Game on the island is unusually scarce, there being no deer, rabbits, or even squirrels, while grouse are not plentiful, which fact is strange, seeing that the natural enemies of these animals, the wolves, coyotes and foxes, are also unknown on the island. Bear are present, but not plentiful. There is no area in the province so well suited for a game reserve—the climate, topography, vegetation and position are ideal—and the island should be stocked and placed under reserve.

Nature has, however, somewhat compensated for the dearth of land game by the bonteous supply of fish found in the sea and small streams, and the clams, rock oysters, abalonies and other shell-fish along the sea shore.

Skincuttle Inlet.

As already remarked, the greater amount of prospecting that has been done an Moresby Island is in the vicinity of Skincuttle Inlet, which was in 1862 the scene of early prospecting. The general geological formation of almost all Moresby Island has been placed as Triassic by Dr. Dawson, with a possibility of some Carboniferous measures. Lithologically, the formation was originally composed of limestones, shales, etc., with heavy deposits of volcanic matter from some local point of issue.

On the lower end of Moresby Island, as seen in the exposures in the various harbors bordering on Skincuttle Inlet, whatever may have been the original formation, it has been subsequently subjected to such an upheaval, with the accompanying faulting and bending, and has been so cut by innumerable feldspathic dykes that no sign of the original formation was traceable. The dyke intrusions are so numerous and extensive as to form the greater part of the rock mass, the sedimentary rocks showing as patches, or isolated masses, without any apparent relation to the next.

The important part, however, is the existing mineral deposits rather than the geological formation, and from the number of mineral locations seen it would appear as though the whole promontory between Huston Inlet and Carpenter Bay was extensively mineralized, the locations so far made simply serving as an index to its general character. The first locations in recent years were made on the shores of Harriet Harbor, from which point prospecting extended to Ikeda Bay and Huston Inlet, and later to Collison Bay and Carpenter Bay.

The mineral claims examined in this vicinity during this trip were all within the area mentioned. Speaking generally of these claims the mineralisation is always found in the immediate vicinity of, if not in the actual contact of, limestone with one of the larger dykes and consists primarily of magnetite, with a greater or lesser amount of chalcopyrite and occasionally considerable pyrrhotite.

Ikeda Bay.

The Japanese firm of Awaya, Ikeda & Company, Vancouver, originally interested in the fishing off the Queen Charlotte Islands, has staked claims on all the hills surrounding Ikeda Bay, and this company was found to be the only concern on the island making any serious attempt at mining, employing 100 men, mostly Japanese, in mining, mining construction and prospecting the claims already staked.

At the inner end of the bay the company has erected a large and substantially built wharf, capable of receiving the largest of the coasting steamships. Connecting the wharf and the mine workings a 36 inch gauge tramway has been built, over which, on cars drawn by horses, the ore is brought down for shipment.

Lily Group.—While some development work has been done on all the company's holdings in the vicinity, the greater amount and all actual mining has been focussed on the Lily group, which consists of eight claims. The development work for the group has been performed on the Lily, upon which the most available outcrop appeared. The outcrop showed up in a small creep, the water of which had washed clear an outcropping of magnetite carrying chalcopyrite. This outcrop occurs in places along the actual contact and elsewhere near the contact of limestone and an igneous rock, apparently a diorite, there being evidence of much movement and some faulting. This deposit, as is the nature of such deposits, does not assume the characteristics of a fissure vein, and is not very clearly defined, nor is it of uniform width or tenor of copper.

The development consists of what is called No. 1 tunnel, which is really an open cut in the creek bed along a contact of limestone and diorite, much altered, along which is a deposit of magnetite with copper pyrites; this has been exposed by the work done for some 30 or 40 feet, and has a width of from one to two feet. It would be difficult to estimate the copper contents of the exposed ore body, as this mineral is far from uniformly disseminated throughout the lead, occurring in bunches of quite rich ore, again scattered through the ore body, while in places the magnetite is practically barren.

Some 400 feet farther down the creek is the No. 2 tunnel, and here most of the development work has

been done, and all the mining, some 700 tons of copper ore having been shipped from this opening in 1907, assaying about 9 per cent. copper, 3.5 ounces silver, and 0.25 ounces gold to the ton. This tunnel had been driven in on the strike of and following the vein for some 160 feet in a S. 10 degrees E. direction. For the first fifty feet the ore has been stoped out up to the surface, the hanging wall, dipping at an angle of about 80 degrees, being supported by timbers, although in the tunnel proper no timber is required. The tunnel is about ten feet wide, and in places the vein-matter occupied pretty well the whole face of the drift.

In the latter part of August the face of the drift was not in ore, the vein having been temporarily lost, but when the property was again visited about two weeks later, it was found that a cross-cut had been driven to the left, towards the hanging wall, in which the vein had been again found and the main drift was being deflected to pick it up.

The ore from the tunnel is run out on cars and dumped on to an incline, at the bottom of which is a picking shed, where the ore is broken and hand sorted, the sorted ore being sacked and run down to the dock on cars drawn by horses, a distance of little over a mile, in which distance there is a drop of about 300 feet. On each car two tons of ore are carried, and one horse is required to bring back the empty car; a driver takes down two cars at a trip.

All the work about the mines is performed by Japanese. The miners working "single handed" are very efficient and compare favorably with the average white miner at this class of work, but the timbermen work very slowly.

There were employed in actual mining operations:— At No. 1 tunnel, about 14 men; at No. 2 tunnel, about 12 men; at No. 3 tunnel, about 8 men.

Chrysanthemum Group.—The same company has also staked out the Chrysanthemum group of eight claims viz.: Peony, Chysanthemum, Rose, Violet, Cherry, Apricot, Bamboo, and Maple mineral claims. This group is located on the southwest side of Ikeda Bay, at an elevation of about 400 feet above, and about half a mile back from the sea; the approach being a gradual slant. On the Chrysanthemum mineral claim there is a large exposure of mineral, some 50 feet long and 20 feet wide and about 15 feet high, consisting of four feet of nearly solid magnetite, with a small percentage of iron sulphide, between defined walls of diorite, and dipping nearly vertical, with strike north and south.

Lying adjacent to this, and to the east, is a zone of from four to eight feet wide of magnetite of a much finer grain, but not as pure, being considerably impregnated with iron pyrites and some copper pyrites. The amount of sulphide in this latter zone is so high as to render it valueless as a commercial iron ore, whereas, as far as developed, the percentage of copper is too low to be profitably worked.

On the Rose mineral claim, of the same group, there is naturally exposed in a bluff a mass of magnetite which, on the surface, is some 20 feet high and 50 feet long. This occurs along a diorite limestone contact, the ore lying horizontal underneath the limestone. In the limestone there is a cave, which was followed in, and up, for over 50 feet, formed by the leaching of a stream of subterraneous water, and in this there is considerable hydrated iron oxide.

Speaking generally, the explorations made indicate that the group contains a great deal of mineralization, masses of magnetite of undetermined sizes, all carrying an appreciable percentage of sulphides of iron and copper, but in no instance has copper in marketable quantity been discovered.

Lotus Group.—The Lotus group, consisting of six mineral claims and also owned by the Awaya-Ikeda Company, is located on the southeast side of Ikeda Bay, about half a mile back from the shore and at an elevation of some 500 feet above the sea. The mineral here exposed is pyrrhotite, the magnetic sulphide of iron, of which a very large body has been exposed with comparatively little work. This exposure is about 20 feet wide and is visible for a height of 20 feet, while 15 feet more depth of mineral is reported as covered by the dump made in the work done. This mass of mineral is bounded on either side by diorite country rock, the contact of which with the pyrrhotite is not sharply defined, but a gradual replacement. Included in the mineral mass are bunches of limestone, although solid limestone formation was not visible. A sample made up of fragments broken from the various large pieces of mineral on the dump assayed three quarters of one per cent. of copper, with traces of gold and silver; while an average sample broken from the exposed face assayed: Copper, 0.4 per cent., with traces of gold and silver. The work done on the group was also more of an exploratory nature than development work, and while the great mass of mineral exposed has no present economic value, it strongly emprasizes the extensive mineralization of the vicinity and encourages further exploration of the group and its surroundings.

Collison Bay.

Collison Bay lies next to Ikeda Bay to the southeast and is separated therefrom by a range of mountains forming a narrow neck of land running out into Skincuttle Inlet.

On August 26th, a gasoline launch was taken from Ikeda Bay around to Collison Bay, but, unfortunately for the writer, the prospectors interested in claims there were absent from their claims and cabins, and it was with some difficulty, and much uncertainty, that the various claims mentioned were found; therefore, it is quite possible that there may be some confusion in the names of claims seen and that some of the workings may have been overlooked.

Meal Ticket.—The Meal Ticket mineral claim and the adjoining claim, the Cash Box, are located on the north side of Collison Bay, about 280 feet elevation and about one third of a mile back from the water. The claims are reported as located by R. J. Leckie in October,1906. On the Meal Ticket a tunnel has been driven about 33 feet, and at 21 feet in cuts obliquely a four foot lead of pyrrhotite, which continues on the left side of the tunnel to the face. The tunnel having been deflected to the right where the mineral was struck, has consequently not cut through the lead, and the thickness of the lead must be inferred from its outcrop on the surface, to the left of the tunnel mouth, at which point a fault plane is observed, along which the lead has been shifted a couple of feet north and its continuation to the east is seen in the dump in the mouth of the tunnel. A general sample of the pyrrhotite exposed was taken and assayed less than half of one per cent. copper, with traces only of gold and silver. The country rock in the vicinity of the tunnel is very much altered volcanic rock, probably originally a diabase.

(To be continued.)

COBALT—PRESENT AND FUTURE.

(EDITORIAL CORRESPONDENCE.)

Four and one-half years have come and gone since the first announcement of the discovery of valuable ore in the Cobalt district. The first authentic information, based upon letters from the Provincial Geologist, was made public in November, 1903. In the autumn of 1904 the Temiskaming and Northern Ontario Railway was running trains into Cobalt, and by the end of the year 190 tons of high grade Cobalt silver ore had been shipped to the smelters.

That the Ontario Bureau of Mines fully appreciated the importance and promise of the new camp is evident, for in the spring of 1905 swarms of prospectors were supplied with accurate geological maps of the district, along with full descriptions of the minerals and of the local conditions. Moreover, travellers were landed in the very heart of the camp in Pullman cars.

A protracted stock jobbing boom began in the summer of 1905. Within two years companies were incorporated and floated with a total capitalization of $212,186,000. Most of these were hopeless wild-cats, schemes designed only to enrich the promoters. Nevertheless the public were bitten, bady bitten. In those days Silver Bird picked the shekels out of willing hands. Cobalt Silver Mountain blossomed and died, Big Ben boomed and "busted," and a horde of possible promoters waxed fat. Their hectic promises they exchanged for coin of the realm.

The year 1907 saw the inevitable reaction. The temporary wave of depression assisted in discrediting Cobalt with the public. The fact that steady progress was being made in the camp itself was unknown or ignored, and investors developed a thorough-going aversion to the very name of the district. However unfortunate this may have been, it was not unmixed with good. Cobalt, left to itself, settled down to work. Mine after mine was added to the shipping list, power plants and mine equipments were ordered and installed in rapid succession, and, today, Cobalt is an industrious camp.

The significance of this progress may be gauged by the following tabulated statement and by other facts adduced below.

1904. Number of shipping mines, 5; tons of ore shipped, 191; total value, $136,217; value per ton, $713.

1905. Number of shipping mines, 17; tons of ore shipped, 2336; total value, $1,485,570; value per ton $636.

1906. Number of shipping mines, 19; tons of ore shipped, 5,836; total value, $3,573,908; value per ton, $612.

1907.Number of shipping mines, 29; tons of ore shipped, 14,851; total value, $5,900,000; value per ton, $411.

For the first three months of 1908, the shipments amount to 4,490.49 tons, the estimated value of which is $2,300,000, or an average of $512 per ton. It will be noticed that the average value per ton shows an increase over 1907. Although much ore was shipped last year, yet it was diluted with heavy shipments of low grade ore. One factor in the enhanced value per ton during the past quarter, is the shipment of concentrates from the mills now in commission. With the addition of new concentration plants the value per ton of the year's shipments will naturally be higher. The same consideration makes the increase of tonnage during the first quarter of the current year all the more significant.

Geological.

The most prominent minerals of commercial importance are native silver, smaltite and niccolite, all associated with a calcite gangue. The sulphides, arsenides, and antimondies of silver also occur, sometimes in considerable quantities. As a rule the veins are small, ranging in width from a fraction of an inch up to, in exceptional cases, two feet. Many of these veins, of all widths within the limits mentioned, are phenomenally rich. They are vertical or nearly so. The country rock, whether conglomerate, slate, diabase, or Keewatin-complex, is hard and compact. Only in rare cases is there any appearance of a crushed zone.

Some of the veins are associated with a fractured zone on either side. In these cases the mineral enrichment has penetrated in minute cracks and veinlets to varying distances. There are instances where the enrichment has extended from eight to ten feet from the main vein.

On all the more important properties several veins heve been formed. The map prepared by Dr. W. G. Miller and Mr. C. W. Knight and issued by the Bureau of Mines shows more than 200 veins in 51 claims. Of these veins, 145 are in the conglomerate, 14 in the diabase and 15 in the Keewatin-complex. It is not well to dogmatize as to the relative importance of these formations; but, after study of their field relations, these facts are significant.

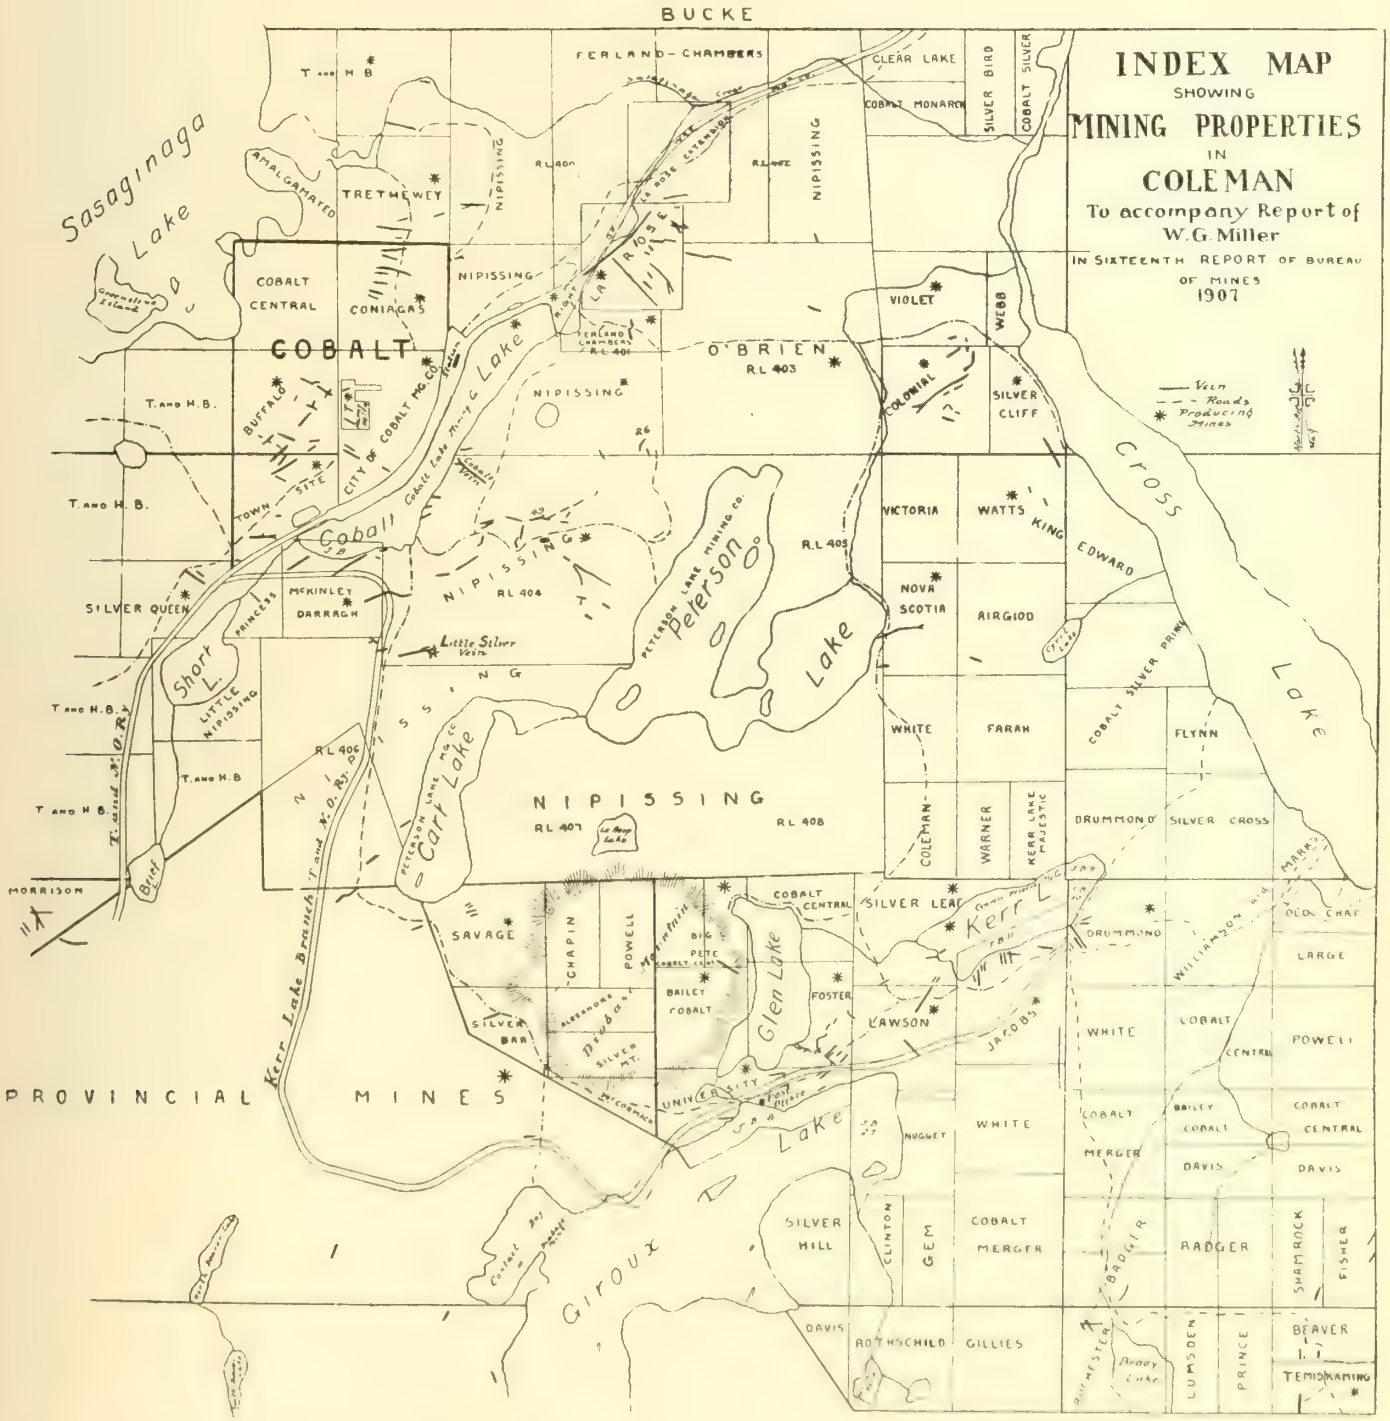
Mining.

The rock encountered in the mines of Cobalt makes hard drilling; but breaks well. Often it is "blocky." Cross-cut and drift walls stand well. No timbering is required except, of course, for shafts, chutes and floors.

In the early days the rich ore was grubbed out in any fashion from underhand surface stopes, the methods bearing as little relation to standard mining as cashing a cheque has to working for wages. Now, however, properties are being opened up in good form.

A remarkably small amount of stoping has been done in the better mines. In some cases large dividends have been paid from the proceeds of ore won in shaft-sinking and lead-stopes. This, perhaps, is the most remarkable feature of the camp.

Most of these mines are waiting for the erection or completion of their concentrating mills. The need of facilities for concentration lies primarily in the fact that many of the vein have associated with them small but visible veinlets of rich material that cannot be recovered from the broken rock by hand-sorting. Mechanical treatment is therefore a necessity. But the pay ore is not confined to the rock carrying these veinlets. Much of the country rock is enriched by microscopic veinlets and segregations. This will require fine crushing and cyaniding.



All the larger mines are working on these problems. The three mills now in operation are tentative in design—experiments on a large and practical scale. Standard designs will be the result of experience and can only be arrived at after patient investigation. But it is recognized that the whole future of the camps depends upon the successful solution of the milling prob-

lem. Rich ore is pleasant enough when encountered; but it does not make a mine. Although Cobalt is a high-grade camp most of the high grade ore is diluted in mining with a relatively large tonnage of milling rock. So the production of the camp is increasingly dependent on its milling capacity.

What the term "high-grade" means can be understood when it is explained that ore assaying less than 1,500 ounces of silver per ton is known as second grade ore. Shipments averaging more than 1,500 ounces per ton have been made. Single car loads have netted the shippers as much as $150,000 and there are pay shoots in the camp that will net $800 per cubic foot. These, however, are by no means the rule. One has but to refer to the annual average value per ton of ore shipped to see that the rich shipments are offset by much material that leaves but a narrow margin of profit, after freight and smelter charges have been paid. This last consideration illustrates the immediate need of more concentrating mills.

Market.

There are now at least eight buyers of the high grade ores produced in Cobalt. Two of these have treatment works in Canada—the Orford Copper Company at Copper Cliffe, and the Deloro Smelting and Reduction Company, at Deloro, Ont. A third Canadian plant, that of the Coniagas Smelter Company, situated at Thorold, Ont., will soon be in running order. In the early days payment was made only for the silver contents, but now arsenic and sometimes cobalt are paid for. For special cobalt and arsenic ores a limited demand exists in Europe and this market is being slowly opened.

Labor.

There is this spring an overplus of workmen. Unskilled laborers predominate. Trained miners are all too scarce. The superintendents and foremen, consequently, have to do much teaching. Naturally this is a condition that time will remedy. Inefficient and untrustworthy men are being weeded out. The camp is gradually attracting skilled miners and as these settle down the mining population of Cobalt will improve. The mine employees number about 2,500. Many nationalities are represented. Before the strike there were many of the best class of Nova Scotian miners. There are fewer now but almost every day the number is being increased. British Columbia and the Western States have contributed their quota. Finlanders, Poles, Austrians, Russians, Italians, and other lesser breeds make up the polyglot total.

The official wage scale of the Mine Managers' Association runs thus:—

Surface Labor.

Surface boss, per day	$3.25
Carpenters, per day	3.25
Carpenters' helpers, per day	2.50
Mechanics, per day	3.25
Pipefitters, per day	3.00
Head blacksmith, per day	3.75
Blacksmiths, per day	3.25
Blacksmiths' helpers, per day $2.50 or	2.75
Engineers, per hour,	.30
Firemen, per hour	.25
Head ore sorters one only at each shaft or ore house, per day	2.75
Ore sorters or cobbers, per day	2.50
Hand miners, per day	2.75
Teamsters, per day	2.50
Hoistmen, per day	2.75
Cage or bucket tenders, per day	2.25
Other surface labor, per day	2.25

Underground.

Timbermen, per day	3.25
Machine men, per day	3.25
Machine helpers, per day	2.75
Cage or bucket tenders, per day	2.50
Other underground labor, per day	2.50

Board will be charged at the rate of $4.20 per week or 60 cents for every day.

Working days shall consist of 10 hour shifts except on Saturday, when the total time shall be 16 hours, 9-hour day shift and 7-hour night shift.

Twenty-five cents per day extra to be paid machine men and helpers sinking in a wet shaft.

At a meeting of the Mine Managers' Association held on December 17th, 1907, the following amendments to the rules of the Association were passed:

"That the scale at present in force be adopted as a maximum scale until further notice, for adults over 21 years of age, and that contracts and bonuses be allowed, and that the rate for blacksmith helpers be $2.50 or $2.75 per day optional with the employer."

The mines are exceptionally dry and generally well ventilated. The pay is good, far better than obtains east of British Columbia. Theer is no general work on Sunday. Board as a rule is excellent and accomodation comfortable. In some cases the managements offer special inducements to married men in the way of assistance in building cabins and houses.

Places of worship there are in abundance. In the two schools there are 450 pupils registered. The average attendance is 350.

Briefly, Cobalt is, from the workman's point of view a desirable camp. It is improving. It requires only the abolition of the "blind pig" to render it a model of decency and decorum.

Equipment.

Steam plants have been installed in 80 properties, with a total boiler capacity of 8,408 horse power. There are two producer gas plants aggregating 425 horse power. Fifty-four air compressors capable of delivering in the aggregate 36,400 cubic feet of free air per minute are in commission on 44 properties. Three concentrating mills are in operation and two are nearing completion.

Plans are being matured for the development and distribution of power from Ragged Chutes on the Montreal river. By means of this or a similar scheme a large saving could be effected.

A majority of the mines co-operate in matters pertaining to labor through a central Employment Bureau, where record is kept of every man engaged or discharged.

General.

Topographically the situation of the mines of the Cobalt district is singularly beautiful. Dotted over knolls and hills, or on the margin of one of the numerous small lakes, the shaft houses and other buildings have commanding views. The custom of painting the name of the operating company on many an office or power house in letters large and legible has been followed—a boon of no small dimensions to the uninitiated visitor.

The actual producing area of the district is comprised in a rectangle measuring roughly 4 by 2 miles. The town of Cobalt, on Cobalt Lake, marks the centre of this rectangle. In many respects the townsite is excellent. The hill on which the town is built slopes gently towards the northwest side of the lake and affords good drainage. But the exigencies of hasty birth and rapid growth have militiated against a due regard for certain of the conveniences of civilization. The noxious incinerator and the malodorous garbage pile make pestilential appeal to the public nose whenever the thermometer rises above freezing. However, Cobalt is now an incorporated town with an enterprising mayor and council, clothed with the power of issuing debentures. It will not be long, therefore, before unseemly smells and offensive sights will be things of the past.

For the accommodation of the travelling public there are two fair hotels. Three Canadian banks have branches in the town. There is no licensed saloon, although the saloon being the least of three evils there well might be.

Both Haileybury and New Liskeard, respectively 5 and 10 miles beyond Cobalt on the T. and N. O. R. R. are residential towns. Many men whose business hours are spent in Cobalt take advantage of the excellent train service to have their homes in the two northerly towns. Toronto is only 330 miles away—a night's run on through Pullman sleepers.

Where two or three are gathered it is even betting that the unsurveyed district south of Larram is a point under discussion. It may therefore be well to conclude this hasty summary with a few words bearing in this new field.

The district, for which no distinctive and comprehensive name has yet been evolved, lies sixteen miles southeast of the town of Cobalt and from two to three miles west of lake Temiskaming.

Late in March of this year the district was visited by a contributor to the "Canadian Mining Journal," who looked over two properties upon which the bulk of the work had been performed. The Keeley (H. R. 19) is one of these and the Haileybury Silver Mining Company (H. R. 16) is the other.

The Keeley vein, two to six inches wide, is opened near the northwest corner of the forty acre lot. The vein has been worked by open cut to a length of forty feet and a maximum depth of fourteen feet. The strike of the vein is E. 28 degrees S. Massive smaltite and, possiblq cobaltite are present. Of wire silver, contrasting with the leaf-silver of Cobalt, there is a good showing. Quartz occurs in the gangue. About two hundred and twenty six bags of ore were ready for transportation.

On the property of the Haileybury Silver Mining Company the vein strikes S. 20 deg. E., dipping 70 degrees east, and is opened near the northeast corner. At the bottom of the forty foot shaft massive smaltite, associated with niccolite and a little native bismuth was found. Calcite, a chlorite, and pink feldspar make up the gangue. In places the vein is five to six inches wide.

Deep snow made close inspection of the district impossible. It is assumed, however, that the country rock of both veins belongs to the Keewatin series.

THE MECHANICAL EQUIPMENT OF THE OTTAWA MINT.

(A paper read before the Mechanical Section of the Canadian Society of Civil Engineers.)

(*Continued from May 1 Issue.*)

Annealing.—The blank annealing furnace is heated in the same manner as the one used for annealing the fillets; but the arrangements for passing the work through is different. The blanks are fed into the machine through

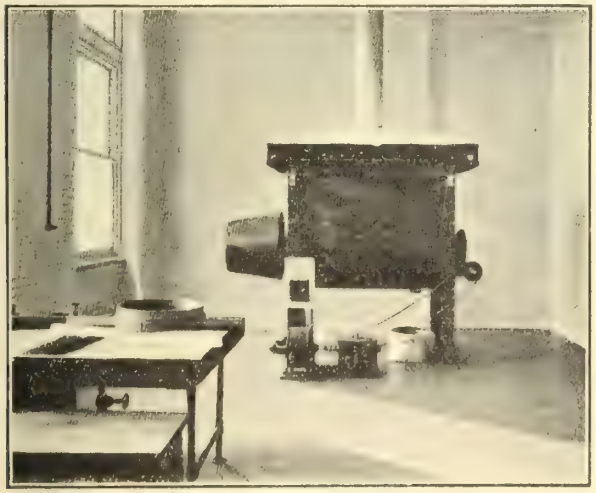


Fig. 15. Rotary blank annealing furnace and sawdust drying plate.

a sheet iron hopper. This hopper is attached to, and revolves with a cast iron hollow cylinder, on the internal surface of which is cast a hollow thread of very coarse pitch. The blanks follow this thread, moving forward slowly as the cylinder revolves, until they fall through an opening which communicates with a shute leading into a vessel containing water. The flame surrounds the cylinder, which is kept at a red heat during the process of annealing. The time taken by the blanks in their passage through the furnace is regulated in the same manner as in the fillet annealing furnace. The blanks are cooled before they come into contact with the air, and oxidation is thus prevented.

Blanching and Cleaning. After having been annealed, the blanks are cleaned in a weak solution of sulphuric acid; washed and dried; they are then ready to receive the imupression from the dies. The solution of sulphuric acid is contained in a copper tumbling barrel, which revolves at about 40 revolutions per minute, and is so designed that it can be tilted for filling and emptying. After treatment by the acid, the blanks are washed in tanks containing hot and cold water, and are then placed in the drying drum with beechwood saw dust. Beechwood is used for this purpose because it contains resin, or other ingredient likely to discolor the blanks or make them adhere to one another. The drying drum is hexagonal in section, the sides made of hard wood, and the ends and attachments of brass. This drum revolves at about 25 revolutions per minute, and the blanks and saw dust remain in it for about ten minutes. They are then tipped into a circular sieve, and shaken

Fig. 16. Tumbling barrel, drying drum, and washing tanks in Annealing Room.

over the hot plate. The mesh of the sieve is large enough to allow the saw dust to pass freely through the bottom, but small enough to retain the blanks. The hot plate consists of a flat sheet iron pan about 6 feet long,

4 fet wide, and with sides 6 inches high. It is supported on four iron legs, and stands about 3 feet 6 inches from the ground. Beneath the pan, and in close contact with it, is a steam coil, by means of which the saw dust is dried, and may be used over again.

Coining.—The coining presses, of which there are three, are of the type in which the pressure is given to

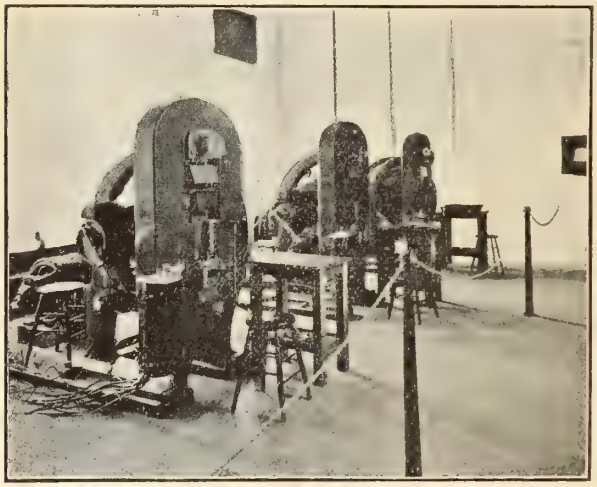

Fig. 18.—Coining presses.

the coins through levers and toggle joints. The hard steel knuckles of the toggle joints are of exceptionally large dimensions, so that coins can be struck at the rate of 100 per minute without any danger of them becoming overheated. Each press is driven by its own motor, and arranged so that the drive can be made either through a belt or gearing. The number of blows struck per

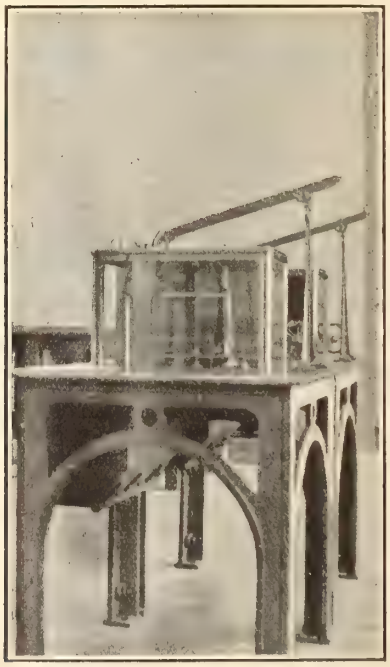

Fig. 18.—Automatic Weighing Machines,

minute can be varied from 30 to 100 by means of a 5-step controller.

The top and bottom dies move up and down, the collar plate remaining stationary. The blanks are placed They are fed to the dies, automatically, by steel feeding fingers, which take one blank at a time from the feed tube, and drop it into the collar, at the same time pushing the previously struck piece into the delivery tube. in the feed tube by the operator, in piles of about 30.

Hitherto, when coining, it has frequently been the case that, for some reason or other, a blank has not been placed between the dies at the proper moment. This may occur through the feed tube being empty, or through a bent blank sticking in the tube. In every case the dies have come together "clashed," and have been rendered useless. It has been known in a large mint for as many as 12 dies to be "clashed" in one day; representing a cost of not less than $22.00, over and above the time taken in changing the dies. As a general rule a pair should be capable of striking about 80,000 pieces before becoming unfit for further use. In order to prevent the possibility of "clashed" dies, a device has been adopted in these presses, by means of which the dies do not come together unless a blank has been placed bebetween them. This device consists of a special clutch between the fly wheel and the main shaft, which is actuated by an arrangement of levers connected with the feeding fingers. In the event of a blank not being fed to the dies, the clutch is released, and the column holding

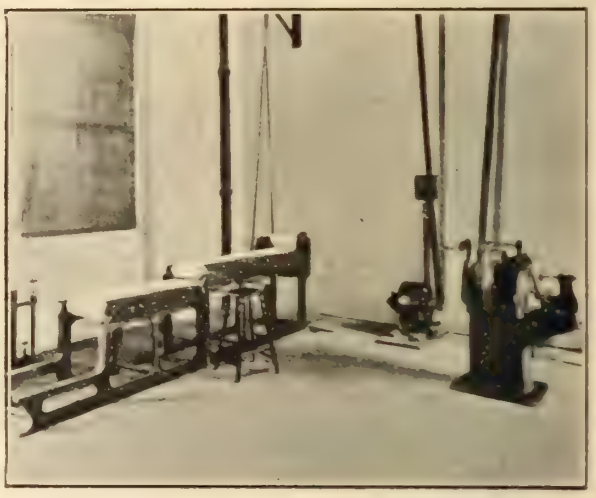

Fig. 19.—Overlooking and defacing machines in Weighing and Examining Room.

the top die is stopped instantly, at its highest point; the fly wheel continuing to run idle on the main shaft. This attachment takes up no extra floor space, and is exceedingly neat and effective. By its means also, single strokes can be made by the press; a very convenient arrangement, when setting a new pair of dies.
the delivery tube and delivered to a bowl placed in the front of the press. The finished coins are forwarded to the examing department, where they are subjected to various tests before they are issued.

Testing.—In the case of gold coins and 50 cent and 25 cent pieces, each one is weighed separately on an automatic weighing machine. The 10 cent and 5 cent pieces are weighed in groups, in a hand scale, against a standard dollar weight; while the 1 cent pieces are weighed, in a hand scale, against an avoirdupois pound, which should contain exactly eighty of them.

The automatic weighing machines are very delicate instruments, the weighing being so accurate that the beam, when fully loaded, will turn with .01 of a grain. Each machine will weigh 20 coins per minute. The coins are fed into a hopper by the attendant. One coin is then pushed automatically on to a flat pan attached

ta one end of the beam; where it remains for 3 seconds; after which it is pushed off by the succeeding coin. During the time it is resting on the pan its weight determines which one of the three shutes it shall drop into when it is pushed off. These shutes lead to three boxes; one for those coins that are to light, a second for those that are too heavy; while a third receives those that are of the correct weight. The latter are taken to the overlooking machine, where they are spread on a travelling band, and carefully examined. Any that are found to be discolored or otherwise imperfect are picked out. The band travels over rollers, and, on reaching one end of the machine, the blanks are turned over automatically, so that the other side of the coins may be examined.

All the gold coins, and the 50 cent and 25 cent pieces that have successively passed through the foregoing tests, are then rung, singly, on an iron block, to find if they have the correct ring, and are not "dumb."

Those coins which have been found to be light, or heavy, or "dumb," or discolored, or in any way imperfect, are destroyed in the defacing machine, and remelted. The defacing machine is of similar design to the marking machine, but whereas the grove in the disc of the latter is a plain one, that in the defacing machine is divided into a series of notches, so that the edges of the defective coins are notched all the way round.

The good coins are delivered to the office, where they are counted into bags by the telling machine. This machine automatically counts, and delivers into a bag, any number of coins, as required. When the desired number has been delivered, the machine stops, until the trigger is again pulled for the next bag. Any number of coins may be counted on this machine, form 100 to 2,000; and any size of coin, from 50 cents to 5 cents.

In addition to the machinery mentioned above, there are several auxiliary machines, for various purposes, throughout the coining department. Weigh bridges, for weighing truck loads of raw material; bullion balances, of various capacities, for weighing the metal during the processes of coining; automatic and hand trying cutter, etc.

For the storing of bullion the Mint is equipped with three strong rooms; one in the Mint Office, one in the Melting House, and one in the Rolling and Cutting Department. These strong rooms are fire and burglar proof, and are fitted with doors, each of which has four combination locks, controlled by triple time clocks, and arranged so that no door may be opened without the presence of at least two officials.

A refinery will shortly be erected in connection with the Mint, in which gold will be treated by the electrolytic process.

MANGANESE IN DEEP-SEA DEPOSITS.

Manganese, as oxide or hydroxide, exists in all deep-sea deposits, sometimes as grains in the ooze, sometimes as a coating upon pumice, coral, shells, and often in the form of nodular concretions with some other substance as a nucleus. The origin of these nodules is doubtful. Their derivation from the subaqueous decomposition of volcanic debris is the basis of the best substantiated theory. The nodules occur in close association with altered volcanic materials, and most abundantly in connection with red clay of similar origin. In composition the nodules vary widely, ranging from 4.16 to 63.23 per cent of manganese oxide.

STRIKE OF GOLD MINERS AT GOLDBROOK, N.S.

On December 18, 1907, the Great Bras d'Or Gold Mining Company, operating at Goldbrook, N. S., posted up the following notice at its mines:

On January 1st, 1908, the following scale of wages will go into effect at our mines at Goldbrook, N. S.:

Miners	$1.75
Muckers	1.50
Laborers	1.25
Engineers, 12 hours	2.00
Amalgamators, 12 hours	2.25

Board can be had at the company's cook house at $3.00 per week.

The company had been paying the miners $2.00 per day, but decided to reduce the wages upon being informed that this rate was 25 cents per day more than the other gold mining companies of Nova Scotia were paying. On January 1st, the miners told the manager that they would not work for $1.75 per day, and it was agreed to continue to pay $2.00 a day to the men who had worked as miners up to that date, but miners who were employed as such after January 1st, would be paid the new scale of wages. On February 20th, when the men received their monthly wages, one miner objected to being paid at the rate of only $1.75 per day. The company claimed that not having worked as a miner before January 1st, having been employed previously as a mucker or helper, he was not entitled to any more. On February 21, the employees made a written demand that the following schedule of wages go into effect at once.

Miners	$2.00
Helpers	1.75
Muckers	1.50

On being told by the manager that this request could not be granted, the men to the number of 22, left the camp, and were paid off the next day. Work was resumed at the mines on March 2nd, some of the old employees having returned at the $1.75 rate, while the places of others were filled.

PRUSSIAN GOVERNMENT COLLIERIES.

The Saarbrucken Collieries, operated by the Prussian Government, produce annually 10,000,000 tone of coal. The system of working is almost entirely the filling-up or stowing method. The introduction of this method has lessened the number of accidents from falls of roof and side materially. Within ten years accidents of this kind have been reduced from 1.54 per 1,000 to 0.61 per 1,000.

The washeries waste, boiler clinker, and other waste materials are flushed into the mine by a current of water in steel and cast-iron pipes. Along with this practice, the longwall system of working is being more extensively used. Timber is saved and the danger of mine fires is largely removed. In spite of this, the following equipment of rescue apparatus is held ready for use: 41 "Draeger" apparatus, 28 "Giersburg," 29 "Walcher-Gaertner," 12 "Neupert" pneumatophores, and 36 smoke masks of various types, together with 170 electric accumulator lamps.

The number of working days for the years 1905-6 was 299.9, the daily output per man, 0.778 ton. The colliery coal consumption was 1,390,747 tons, or 12.9 per cent. of the output.

NOTES ON FUEL ECONOMY AND ITS APPLICATION TO NOVA SCOTIA.

By A. A. Hayward, Halifax.

(*Continued from last issue.*)

It is only within a few years that large types of gas engines have been on the market. To-day the modern gas engine is the cheapest and most efficient power known. By the Mond producer process, about 15,000 feet of gas can be generated from one ton of coal, or 15 times more than by ordinary methods. This gas would have calorific value of 22,500,000 B.T.U. and a heating power of 26,400,000 B.T.U. Of this thermal heat an ordinary steam engine only succeeds in turning into useful energy about 6 1-2 per cent. or 1,616,000 B.T.U.; while a gas plant having a combined efficiency of 25 per cent. and a mechanical efficiency of 85 per cent. multiplied by 25 per cent. would secure in useful energy 21.25 per cent. at the engine shaft, thus showing an efficiency of nearly 300 per cent. over the ordinary steam engine. Mr. Byron Donkin says it has now been proved by experience that a good gas engine turns about double as much heat into work as a good steam engine.

In operating a modern gas producing plant of large unit, less than one pound of coal is required to produce one B.H.P.H., while to obtain the same results by a steam plant would require from 2 to 6 pounds, depending largely upon the size and kind of plant.

A series of tests made of gas producers and engines using 1 1-4 pounds of coal per H.P.H. show the yearly cost of operation a gas plant to be as follows:—

Coal at $3.50 per ton, cost of one horse-power..	$5.83
Coal at $4.00 per ton, cost of one horse-power..	6.67
Coal at $5.00 per ton, cost of one horse-power..	8.33

A further illustration of fuel economy is shown by a 500 horse-power plant used for generating electricity:—

500 horse-power unit.	
Fuel cost, per ton	$2.36
Consumption indicated horse-power, lbs.	.78
Consumption per kilowatt hour, lbs...	1.40
Cost of fuel per indicated horse-power hour	.04
Cost of fuel per brake horse-power hour	.055

Result of a test made by the United States Geological Survey of No. 2 Wyoming lignite:—

Hours of duration	30
Average power required to drive auxiliary machinery	16.4
Equivalent in pounds in dry coal per hour	51.2
Total dry coal used in producer during the test	10,968
Total refuse in coal	2,509
Total coal consumed	8,449
Dry coal consumed per hour in producer	365.3
Equivalent to dry coal used by the producing plant	416.5
B.T.U. from pound of dry coal	10,656
B.T.U. from dry coal as fired per hour	3,892,600
Total gas produced at 62 degrees and 14.7 pounds pressure	447,700
Total gas produced per hour	14,923
Total cubic feet pas per pound dry coal consumed in producer	40.9
Per pound equivalent dry coal used by producer plant	35.8
Average electrical horse-power available for outside work	184.8
Average electrical H.P. at switchboard	201.2
Brake H.P. developed at engine	236.8
Efficiency—	
Of conversion and cleaning gas	.58
Of producer plant	.50
Dry Coal Per H.P. Hour—	
Pounds consumed in producer per elec-horse-power available	1.98
Pounds consumed in producer per electric horse-power at switchboard	1.82
Pounds consumed in producer per break horse-power at engine	1.54
Pounds equivalent used by producer plant per electric horse-power	2.25
Pounds equivalent used by producer plant per switchboard	2.07
Pounds equivalent used by producer plant per break H.P. at engine	1.76
Composition of Coal—	
Moisture	9.44
Volatile matter	35.02
Fixed carbon	34.82
Ash	20.72
Sulphur	3.91

The remarkable results obtained at the fuel testing plant of the United States Geological Survey at St. Louis supply abundant material for serious thought. While the report may be understood by engineers and those accustomed to technical detail, these details are somewhat confusing and obscure to the ordinary layman. The accompanying scale of comparisons will assist in making the results fully understood (paper by Mr. Marius R. Campbell).

Seventy-two tests were made under practical conditions, and made from samples of coal ranging in quantity and moisture from the lignites of North Dakota to the best coal of Virginia and Pennsylvania. Among the noticeable features of these tests was the absence of smoke. The sulphur contents varied from 1 to 7.36, and the ash was as high as 23.44. Notwithstanding these high percentages, satisfactory results were obtained. In fact, coal carrying a much higher percentage of ash and sulphur could have been used, providing the coal was not so fine as to pack in the producer. Lump coal gave no better results than fine, while under a steam boiler the size of the coal was of much importance.

The table shows the results obtained by the producer and steam plant, the first block in the diagram being the standard representing one electrical horse power per hour. The block in the left-hand column shows the frac-

tion of an electrical horse-power that was produced by one pound of coal as fired under the boiler. The second columns represents the fraction of an electrical horse-power per hour, generated by one pound of coal as fired in the producer; while the relative efficiency of the coal used in the producer plant, as compared with that used under the boiler, is shown by the size of the blocks and the ratio in the central column.

It will be seen that by each test one pound of coal used in the producer developed more power than the same coal fired under a steam boiler, and in some cases more than three times as much, the ratio running from .96 to 3.34.

Another striking feature of the test is the result obtained from peat fuel. More power was generated in the producer with peat than from the best Virginia coal used under a boiler. The peat gave values of .299, .308, .355, .388, .330; while by the best coal only .287 of an electrical horse-power was obtained under the boiler.

The report admits that, had the steam been compounded and condensed, much better results would have been obtained. But improvements could have been made in the producer plant. As the tests were made with a producer using forced draft, the tar was not consumed, but saved as a by-product. It must thus be seen that this style of producer was not the best for soft coal, as one consuming the tar would generate a larger volume of gas, and would recover as a by-product a large percentage of sulphate of ammonia.

A test at St. Louis of Ohio coal demonstrated that this coal, when gasified and burned in an internal combustion engine, producer 286 times as much energy as when the same coal was consumed under a boiler.

An average of fourteen separate tests made from thirteen different grades of coal shows that to generate one electrical horse-power by gasified fuel and internal combustion required 1.70 pound of dry coal per hour, while to create the same energy by external combustion, it required 4.29 pounds per hour; showing an actual waste, by the use of steam, of 2.59 pounds of coal per hour electrical horse-power. These results are remarkable when we consider the quality of coal used.

During the same year the coal mines in the State of Ohio produced 6,597,600 tons of coal. Of this amount 4.880.740 tons were used for power purposes, and excepting the efficiency of gasified fuel and internal combustion over external combustion to be but 50 per cent., the saving by the former method would equal 2,449,370 tons. This, at $1.60 per ton at the mine, would mean an annual saving to the State of Ohio of $3,904,592. How strongly this result reminds me of the situation in Nova Scotia!

At a test made of the Mond gas producer plant at Heyshan, using one producer and running two engines at full load, the I.H.P. was 509, the B.H.P. 432, and the full consumption 2,213 pounds; equal to 1.09 pounds per I.H.P. per hour and 1.28 pounds per B.H.P. The fuel used was small bituminous coal.

These tests are of much value, as their results, together with other valuable data that are being supplied from many different sections, point strongly to gasified fuel and the internal combustion engine as our future heat and power.

So near do the conditions in Ohio approach those existing in Nova Scotia that we are justified in accepting the economic results as final, and can apply the same line of determinations to our own situation. During the same year the mines of this province produced 5,800,000 tons of coal, which had an average value of $2 per ton at the mines, or a gross value of $11,600,000. To this sum an additional $2 per ton, or $11,600,000, should be added to cover costs of transportation, handling, commissions and middlemen's profits, making a grand total of $23,200,000, the sum actually paid by the consumer for 5,800,000 tons of coal. Of the 5,800,000 tons produced, 60 per cent., or 3,480,000 tons, were used for power purposes, the balance, 40 per cent., is represented by 2,320,000 tons consumed for domestic purposes. Of the 3,480,000 tons used for power purposes, about 9 per cent. of the actual thermal energy of the coal was utilized, while from the 2,320,000 tons of domestic coal the thermal heat utilized did not exceed 5 per cent.

If the amount of coal required for power had been converted into Mond gas and burned in an internal combustion engine (one having a combined efficiency of 20 per cent), 1,555,000 tons would have been sufficient to accomplish the same results as was secured from the 3,480,000 tons, while a large amount of economy would have resulted in our domestic requirements, as 1,150,000 tons would have been sufficient to accomplish the same results as we obtained from the burning of 2,230,000 tons, thus showing that by the use of gasified fuel, 2,705,000 tons of coal would have been sufficient to accomplish the same results as those secured from the 5,800,000 tons, our annual output. This would have resulted in a saving to the Province of Nova Scotia of 3,095,000 tons of coal, having a cash value at the mine of $6,190,000.

Continuing our economic policy, if we should add to our gasification plant one for the recovery of the sulphate of ammonia contained in the coal, the yield of which would have been about 80 pounds per ton, the total recovery at the present market price would have resulted in a net profit of $2,900,000. This sum deducted from our coal bill would leave a balance of $3,290,000, the net cost of our annual bill for heat, light and power, delivered in the gas holder at the mine and ready for delivery, as against $11,600,000, the present cost.

That we are approaching a period of economic transition, no one familiar with our national aspirations will question, and no subject should receive more serious consideration than the generation and distribution of the heat and power contained in our fuel deposits. The scientific investigator, capitalist and consumer are all beginning to recognize their individual responsibility. The latter expects the former to utilize a far larger percentage of the constituents combined in the raw material, and to do so on a scale of efficiency that will enable the finished product to be delivered at his door by the most direct means and at the lowest possible cost.

When these principles have been fully recognized and firmly established as a basis of our industrial life we shall apply them directly to our fuel deposits by establishing large central plants at collieries for the gasification of coal, and the recovery of the valuable by-products they contain. We shall construct transmission pipe lines to all points of large consumption. We shall further extend our economic principles by individual distribution of gas fuel for all domestic purposes, while by the adoption of gas engines we shall generate and distribute electricity for power and light. We shall then avoid paying tribute to transportation companies, teamsters, coal handlers, middlemen and the various other sources of expense we have now to contend with, all of which increase the cost of our fuel beyond its original cost of production; and above all, we shall escape paying a proportionate part of these various profits on

ashes and stone from which we now receive no benefit. We shall then receive a far larger equivalent in heat for the money expended. Power will be supplied in large units at prices that would defy the competition of Niagara. The smoke and dirt nuisance would be entirely eliminated, while our morning slumbers (for under such ideal conditions they would be peaceful and prolonged) would not be disturbed by harrowing dreams of neglected duty due the furnace, or the discordant cry of "coal, coal" by the hawker.

When the morning is bright with realizations of such ideal conditions, Halifax will be in a position to offer the manufacturing and industrial world advantages unequalled on the Atlantic seaboard, receiving as she will, heat, light and power from the mines of Pictou County at prices that will defy competition.

COLLAR AT No. 1 ALLAN SHAFT.

By H. E. Coll, Stellarton, N.S.

(Read before the Mining Society of Nova Scotia, 25th March, 1908.)

When sinking was commenced at No. 1 Allan Shaft in April, 1904, it was found that a considerable thickness of water-bearing sand, overtopped with clay, had to be penetrated before reaching rock. It was decided to use temporary timbering and continue sinking, leaving the permanent work to be put in when the sinking was finished. Consequently the first of June, 1906, we were ready to commence work on the following proposition:—

The original shaft opening, 12 feet by 24 feet, had been timbered with 10 inch by 10 inch hemlock, having 4 foot 10 inch centres, for a distance of 23 feet. At this point the walls had given way and the remaining distance of rock had been skin timbered and piled laterally. The shaft opening had twisted and was out of line, the south and east sides being closed in over 18 inches. On the surface the ground was broken back for a distance of 20 feet on the east side, the west side being fairly good. Two 14 inch by 30 inch timbers had been placed across the shaft, and the weight of the headframe rested on these. This headframe was 40 feet high and built heavy enough to hoist two tons weight.

The shaft was making an average of 30 gallons of water per minute, and this had to be handled daily, so that it was necessary to carry this headframe independent of the shaft timbering and collar work, and until the top section would be placed, the guides and shaft timber could not be moved. Commencing 300 feet from the south end of the shaft an incline was driven towards the shaft, so as to tap the shaft opening 20 feet below the surface. The material was handled by a horse and dump car, having a capacity of one cubic yard of material. This incline was cut from the surface and securely timbered. When the south end shaft timbering was reached, a turning sheet was put in and the material was taken out to that depth all around the shaft for a width of 5 feet 4 inches. This was done by benching, and as soon as sufficient space was gotten all around the shaft, a set of round sticks was placed, "log cabin fashion," the ends projecting 2 feet 6 inches, and drift bolts being driven at the corners and centres, on both sides and ends. As fast as space was made another set was entered from the bottom and packed into place. Braces were then placed on the corners and centres between the logs and the square shaft timbers. In this manner we reached the bottom of the incline, or 20 feet from the surface, but the ground on both east and west sides had broken and we were carrying the weight of the walls on our timber. The shaft timbers were then taken out, and as the 28 foot span was too much for our side logs to carry, we placed cross sticks on the shaft centre line, in such manner as not to interfere with permanent timbering coming up. The next 20 feet was a sandy mud that, if given an opening, would run like water. After two attempts we abandoned further sinking until we could get piles driven, as the surface had begun to break back a distance of 30 feet. In preparation for such an emergency, we had a pile driver and piles on the ground, and work was immediately commenced on the northeast corner by driving a pile between the projecting ends of the logs. Then a row was driven down the side around the south end and so on to the northeast corner again. The piles were yellow pine creosoted, 40 feet to 50 feet in length, and were pointed with steel shoes, made of one-quarter inch plate. All told, one hundred and twenty-four piles were driven around the shaft, and it was decided these should be sufficient to enable us to continue sinking. In order to take the weight of the "log cabin" timbering, we put in concrete "dead men" 50 feet back from the shaft corners and anchored the timbering by 1 inch wire rope. A tension of about eight tons was put on the four ropes. Before excavating below this timber 3 inch by 6 inch by 5 foot piles were driven at an angle of 10 degrees from the vertical, thus bringing the lower ends against the piles. We then took out sufficient muck to get in a set of timbers. In this way we secured ten more feet. But at this point we found that nearly half the piles that were driven had sheared and the upper end had then driven down inside the timber line. By this time the ground was broken on both east and west sides for a distance of 30 feet. As fast as the cracks opened up they were grouted full, but a rain at any time during these 24 hours would have probably caused serious trouble.

Fourteen inch round timbers were hastily swung into place, and braced across the shaft. These, of course, had to be kept clear of the No. 1 compartment, and the vibration of the headframe when water was being hoisted required them to be watched and tightened almost hourly. After placing ten braces we again began excavatin. We had to cut out the misplaced piles, drive plank piling and place the round timbers as closely following one another as possible, and in fact the different jobs overlapped each other. Most of this work was done below the surface of the muck, in order to prevent it draining out from behind the walls. The last nine sets of wall timbers had to be spliced, as the plates were too long to swing between the bracing, and this required centre bracing for each splice. These were placed in thirty-six hours, at the end of which time the shaft was squared up on rock at a depth of 52 feet. It was recognized that no time was to be lost, as the timbering was showing

grave signs of strain. The inch ropes were buried out of sight in the wood, and three of the cross braces were split. Fortunately everything and everybody was ready, and before all the muck was out of one corner the concrete was pouring into the other. As soon as a foot deep layer was on, three sets of yellow pine shaft timber were placed and braced at the corners and centres against the wall timbers. On top of this foot of concrete, and each succeeding foot, four 56 pound steel rails were placed one foot from the shaft plates and ends. These rails were 16 and 22 feet long, the shorter ones being placed at the ends and overlapping the longer ones. We found that the removing of cross braces, placing of shaft sets and rails gave sufficient time for the concrete to set.

The following means were used in handling the material:—

For hoisting water the main sinking engines were used, and when not utilized for water a muck bucket was hung and so used for mucking out for the timbering. The most of this, however, was done by the original sinking engines: a pair of 10 inch by 12 inch second motion Lidgerwoods. The rope led from the drum to the foot of a 30 foot derrick, which would swing one hundred and eighty degrees. A shakle and pin fastened to either a muck bucket or a hitch chain, depending on what was being handled. All the timber and rails were handled directly to place by this rope. The water was carried by troughs to inside the shaft line, until the stream would be overtopped by the concrete. At all times the concrete was kept thin enough to penetrate any crevices or open place behind the log cabin timbers, and "men" constantly rammed in to ensure compact setting.

The concrete for this work was of the following proportions:—

One barrel cement (350 pounds).
Three barrels sand.
Two barrels broken sandstone.
Two barrels slag.

This is equal to about one cubic yard of concrete rammed in place. The capacity of the mixer was five yards per hour, but owing to timbering, placing of rails, and other interruptions, the average was about half this amount. The crushed rock and slag were hauled and dumped on one side of the machine and the sand on the other. Each batch took a half barrel of cement, and all the material was loaded by hand and dumped into the mixer. From the machine it was conveyed by separate delivery chutes made of 10 inch galvanized tubes. One connecting piece was used as a switch to throw the concrete to any point desired.

The top section of the collar was widened out to include the foundations for the bankhead and headframe, as shown by the accompanying plan, and is, of course, counted in the cost of the shaft collar.

The weight of the various materials used in concreting are as follows:—

	Tons.
Cement	296
Stone	708
Slag	266
Sand	705
Steel	16
Total	1,991

The shaft sets required 36,400 feet of yellow pine, and in piling, staging and timbering 30,450 feet of spruce timber was made use of. One hundred and eight logs were used in the log cabin sets, and 124 piles were driven.

The cost of the completed shaft collar is as follows:—

Cost of labor—		
Excavating		$1,826.66
Piling		677.21
Concreting		1,929.80
Timbering		496.85
Total		$4,930.52
Cost of Stores—		
Piling		$1,225.63
Timbering		1,396.90
Rails		931.25
Sand		595.80
Rock		693.75
Cement		2,756.25
Total		$7,599.58
Total		$12,530.10
Cost per foot, depth of collar		$245.69
Cost per cubic yard of concrete—		
Labor	1.14	
Stores	2.39	
		$3.53

The work in the shaft was done by three eight-hour crews of eight men each, having two 12-hour foremen. The surface men worked two shifts of 10 hours each. Fourteen men were required in delivering and mixing the material for concrete. The work itself would not have been so difficult were it not for the several propositions which arose.

I will mention one trouble which caused us considerable anxiety: We had no ventilation in the shaft, and as a result a low barometer would bring the gas up the shaft in considerable quantities. All night work was done by electric reflectors, placed in the open air, and safety lamps were used in the bottom. The greatest precaution had to be taken to keep visitors from lighting matches or smoking in the vicinity of the shaft.

The hoisting of water was another matter that gave considerable trouble. A bucket holding 200 gallons and having a wing valve in the bottom was used, and each time this was landed on the bull chain it shook the ground all around the shaft and kept the mud constantly moving. The water was carried away in a large trough, and try as we might we could not present a little leakage when a bucket was dumped.

Another time the rope broke just as a bucket of water reached the top and it dropped the 1,500 feet to the sump without touching a timber on the way down. We lost five hours fishing that bucket up.

When finished we had the satisfaction of knowing that a big job had been well done, for not a drop of water showed on the face of the shaft timbering, and to-day that collar is bearing the weight of a steel headframe 110 feet high without showing a sign of any strain.

Mr. J. E. McEvoy, who has resigned from the staff of the Crow's Nest Pass Coal Company, Fernie, B.C., was presented with a handsome travelling bag, fitted with a gold pendant set with pearls and diamonds, and Miss McEvoy a solid gold braclet. Presentations also were made to Mr. McEvoy by the directors of the company, by the Fernie Club and by the Kootenay Rifles.

A Partial Bibliography of Publications Referring to the Geology and and Mineral Resources of Alberta, British Columbia and the Yukon.*

By J. C. Gwillim, Kingston, Ont.

The following classification of literature dealing with the exploration, geology and mining of these regions, is not complete. It has been compiled chiefly from three relatively accessible sources, namely, from the reports of the Geological Survey of Canada, and the Provincial Bureau of Mines, and the Canadian Mining Institute transactions.

The inclusion of some purely geological reports of the more remote districts seemed advisable, as offering first aid to those who go into them with the purpose of mining.

The reports of the Geological Survey provide our chief source of information in respect to the economic geology of these areas; and it may be stated that Alberta, British Columbia, and the Yukon, have received a great service from the Canadian Geological Survey, from the days of Richardson and Dawson, to the present summer, when eight field parties were working in these provinces. The publications of the Geological Survey are, in most cases, free, and will be sent on application by the Library of the Department at Ottawa.

The Annual Reports of the Provincial Mineralogists contain much statistical information relating to production and progress, together with reports or summaries of the conditions in the respective mining divisions. There are also incorporated in these volumes special reports upon mineral or coal areas, by the Provincial Mineralogist, the Provincial Assayer, and others competent to investigate them. The British Columbia reports, and also various bulletins on, and maps of, the mining districts of the Province can be obtained free, or for a small sum, on application to the Provincial Bureau of Mines at Victoria.

The transactions of the Canadian Mining Institute appear to round out our field of information, by giving detailed studies of mines, mining geology and mining operations. This is a source of information which is likely to increase as the provinces develop. Volume V. is especially valuable in papers relating to operations in British Columbia. It would make this paper too cumbersome if one ventured into a description of the material within the titles cited. Attention, however, may be called to those having an asterisk, as affording much detail information concerning the area or areas to which they refer. The work of Dr. G. M. Dawson is always valuable, and his observations cover a large portion of the country here considered.

Concerning the selection of papers and authors in this compilation, I am largely indebted to the Geological Indices of D. B. Dowling and F. J. Nicholas, also to the index of "The Canadian Mining Journal," up to Volume VI. Any important omissions may be added. The list is lengthy, but it is a tolerably available one.

The abbreviations used, are:

G. S. D.—Geological Survey Department, Ottawa.
M. M.—Report of the Minister of Mines, Victoria.

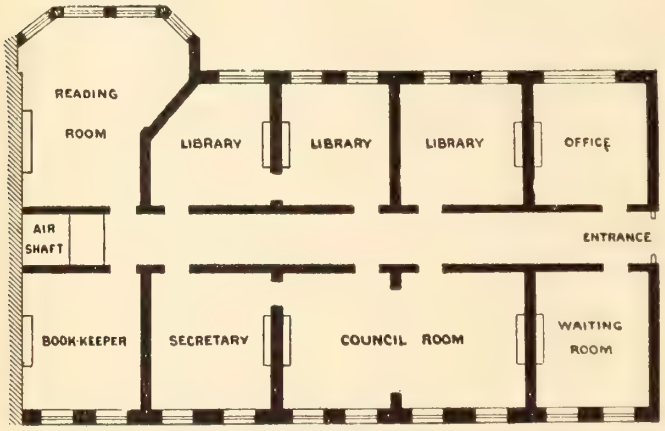
(To be continued)

THE NEW PREMISES OF THE IRON AND STEEL INSTITUTE.



Owing to the steady growth of the membership of the Iron and Steel Institute, with the increasing clerical work thereby entailed, and to the expansion of the Institute library, which now contains several thousands of volumes, the Council decided, early in the current year, to secure more commodious offices, and to effect certain improvements in the internal arrangements with the object of providing additional facilities for the members. An opportunity fortunately presented itself for obtaining a lease of the spacious offices, in the same building, formerly occupied by Sir Douglas Fox & Partners. The acquisition of these premises presented numerous advantages, amongst which the fact that the address would remain unchanged, had much weight with the Council. Negotiations were therefore opened with the Westminster Trust, who are the landlords of the premises, and a satisfactory arrangement having been arrived at, the Council concluded an agreement at their meeting in February.

The new premises consist of a suite of ten rooms, on the first floor of No. 28 Victoria street, having precisely the same outlook as the recently vacated offices, and access being obtained from the same main entrance and staircase. The Council have also obtained the use of a storeroom, conveniently situated in the same building, on the sixth floor.

A plan of the new offices is shown in the figure herewith. The entrance is immediately opposite that of the old premises, and affords access to a spacious hall nearly 70 feet in length. The rooms have been decorated throughout in white enamel, with distempered walls of pale straw-yellow color, which ensures the maximum radiation of light, and enables an effective display to be made of the extensive collection of portraits and paintings possessed by the Institute.

To the left, on entering the hall, is a suite of five rooms overlooking Victoria street. The first room is fitted as a waiting room, and its most interesting feature is the large showcase containing the collection of early specimens of Bessemer steel presented to the Institute by Sir Henry Bessemer. Amongst other objects of interest on view in this case are short pieces of a 100 pounder gun tube made of Bessemer steel, a 74 pounder steel projectile formed in a hydraulic rolling mill of novel construction, designed and worked by Sir Henry Bessemer, part of a Bessemer steel rail rolled

at the works of the London & Northwestern Railway Company, and a portion of a steel rail twisted into a complete spiral, from end to end, without producing fracture. Two interesting specimens are pieces cut from the two first rails of Bessemer metal ever rolled, the metal having been made from Blaenavon grey foundry pig at Sir Henry Bessemer's experimental works at Baxter House, London, in 1856. A sample consisting of the earliest experimental example of metal converted by the Bessemer process is also shown, the resulting ingot having been rolled at the Royal Arsenal at Woolwich into a flat bar. This bar was made in about the month of June, 1856, and was among the samples of Bessemer metal exhibited at the meeting of the British Association at Cheltenham on the 13th August, 1856. With the exception of this bar, all the other samples shown on that occasion have been lost. There is also a small model gun forged from one of the first Bessemer ingots which were made at the works of Messrs. Bessemer & Company at Sheffield. An analysis of the metal of which this gun is made was conducted by Mr. Edward Riley, when it was found that it yielded 99,787 per cent. of pure iron, and was therefore equal in qaulity to some of the highest brands of Swedish bar iron. Another showcase contains a collection of medals and of the badges which have been issued at the various meetings of the Institute.

Plan of the new Iron and Steel Institute.

Suspended around the walls of the waiting room are portraits of Henry Cort (the inventor of puddling and of grooved rolls), George Thomas Clark (one of the trustees of the Institute, 1880-1898), Alexander Thielen (vice-president 1896), and Benjamin Walker (member of Council, 1889-1890), together with diplomas gained by the Institute at various exhibitions in which it has participated, including those of Paris, St. Louis and Milan.

The two adjoining rooms have been thrown into one, and form a spacious Council room. In a prominent position of this room stands a life-sized painting in oils, by H. T. Wells, R.A., of the seventh Duke of Devonshire, the first president of the Institute. At one end of the room is suspended a large oil painting, by Rudolph Lehmann, of Sir Henry Bessemer (president, 1872), at the period of his invention of the Bessemer process. At the other end hangs the portrait, in oils, of Edward Williams(president, 1879-81), presented to the Institute by William Jenkins of Consett. The Council room also contains the portraits of the past-presidents of the Iron and Steel Institute, viz.: Sir Lowthian Bell, Bart. (1873-75); William Menelaus (1875-77); Sir C. William Siemens (1877-79); Edward Williams (1879-81); Josiah Timmis Smith (1881-83); Sir Bernhard Samuelson, Bart. (1883-85); John Percy (1887-89); Lord Airedale of Gledhow (1889-91); Sir Frederick Augustus Abel, Bart. (1891-93); Edward Windsor Richards (1893-95); Sir David Dale, Bart. (1895-97); Edward Pritchard Martin (1897-99); Sir William Chandler Roberts-Austen (1899-1901); William Whitwell (1901-1903); Andrew Carnegie (1903-1905); Robert Abbott Hadfield (1905-1907). The Council room also contains a portrait of Mr. W. H. Bleckly, hon. treasurer, and albums containing a collection of photographs of members of the Institute.

A door of communication from the Council room affords access to the secretary's room, while the last room on this side of the hall is used as an office for the Institute's accounts and correspondence. On the western side of the hall is a large reading room and lounge, in which members may consult current periodicals, conduct correspondence, and meet each other for conversation or consultation. Smoking is allowed, and comfortable lounge seats have been provided, the Council being desirous of encouraging members to use the room as a meeting place. On the walls of the reading room are displayed portraits of the Bessemer medalists of the Institute, including Robert Forester Mushet, Peter Ritter von Tunner, Peter Cooper, Sir Joseph Whitworth, Bart., Alexander Lyman Holley, George James Snelus, Sidney Gilchrist Thomas, Richard Akerman, James Akerman, James Riley, John Devonshire Ellis, Henri Schneider, William Daniel Allen, Hon. Abram S. Hewitt, Lord Armstrong, C.B., Arthur Cooper, John Fritz, John Gjers, Henry Marion Howe, Hermann Wedding, Richard Price-Williams, Henri de Wendel, John Edward Stead, Friedrich Alfred Krupp, John Oliver Arnold, Floris Osmond, Johan August Brinell.

In this room also stands a handsome marble pedestal, surmounted by a marble bust of F. Krupp (hon. member of the Institute), bequeathed by Mr. Alfred Longsden, and a bust of the late Sidney Gilchrist Thomas. Over the mantelpiece is a small bust in cast iron of Professor A. Ledebur (hon. member of the Institute).

The three adjoining rooms on this side are devoted to the library of the Institute. In the last of the three provision is made for special research for the purpose of enabling members desirous of consulting works of reference, or the files of mining and metallurgical periodicals, to do so in quietness and privacy. In this room a card catalogue to the library is available, and the current files of some hundred and fifty technical journals are placed in boxes easy of access.

The last room of this suite (the first on the right, on entering) is the general office for inquiries, etc. In the new premises effective ventilating apparatus is provided, and the hall and rooms are lighted by Osram electric lights. There is telephonic communication between the various rooms. In case of fire there is an iron door to shut off the premises from the rest of the building, and fire-extinction apparatus is provided.

It will be seen from the foregoing that the new premises are considerably larger than those just vacated, and it is hoped that not only will the increased facilities thus provided attract the London members of the Institute who may have occasion to avail themselves of them, but that the members resident in the country and abroad may find them increasingly useful when they visit the metropolis, and thus realize the objects which the Council have had in view in planning and carrying out the necessary alterations.

EXCHANGES.

Mines and Minerals, April 1908.—Cyaniding Cripple Creek ores is the subject of a paper by F. L. Barker in this number of Mines and Minerals for April.

The rates for ore treatment offered by the Golden Cycle Mining Company in their independent custom mill aer as follows:

Golden Cycle Rates.	Per ton.
Up to $8 inclusive	$4.00
$8 to $10	4.50
$10 to $15	5.25
$15 to $20	6.00
$10 to $25	6.50
$25 to $30	7.00
$30 to $40	7.50
$40 to $60	9.00
$60 to $100	9.00
$100 to $150	12.00
$150 to $200	13.00
$200 to $300	13.50
Over $300	13.50*

*Plus 1 per cent. assay value.

The competitive rates of the United States Reduction and Refining Company have been made slightly lower than these. The result of this rivalry has been highly beneficial to the camp.

The costs of mining, including stoping, developing and sorting are nowhere less than $8 per ton, and in many cases are higher. Millions of tons of low grade ore are slowly becoming available, as heretofore no ore running less than $20 has been shipped. Cyanidation is believed to be the key to the problem.

An analysis of the Golden Cycle ore may be quoted here:

Silica, per cent.	55.98
Alumina, per cent.	17.09
Iron, per cent.	3.44
Magnesia, per cent.	0.47
Lime, per cent.	0.71
Sulphur, per cent.	1.77
Gold per ton, oz.	0.98
Silver per ton, oz.	0.62

The principal primary miners are calaverite, tetrahedrite, sylvanite, barite, quartz, pyrite, fluorite, calcite, dolomite. The secondary minerals are gold, gypsum, psilomelane, limonite, alunite, and epsomite.

These secondary minerals occur in the oxidized zone and are amenable to cyanidation. But the ores containing the tellurides of gold and silver have to undergo preliminary treatment, since compounds of tellurium are not soluble in cyanide solutions. Roasting is resorted to for this. Bromo-cyanide has not met with much success.

The Isabella cyanide mill, working low grade dump ore, gives a four-day leach. The tank capacity is to be increased so as to permit of a six-day leach. A 9 inch by 15 inch Blake crusher, fed by gravity, takes the ore from the bin. At the crusher, lime is added at a rate of about 5 pounds to the ton of ore. The ore then goes to a 16 inch by 36 inch Davis roll and thence to two 14 inch by 27 inch Davis rolls. It is then passed over a ¼ inch mesh bumper screen, the oversize from which is returned to the last set of rolls, the undersize going by a belt-conveyor to a storage bin of 200 tons capacity. Six leaching tanks, 5 feet deep, 30 feet diameter, holding 125 tons and arranged in a single row are filled in 4 hours. The four end tanks are filled by the belt conveyor, the two middle tanks direct from the storage bin, which is placed just above them.

Strong solution, 4 pounds of cyanide to the ton of water, is added first, followed by a 3 pound, and then a 2 pound solution, and finally by a wash of water. As the solutions are drawn off they pass pass though a battery of nine zinc boxes to a sump below. The leached sands are shovelled through manholes in the tank bottom on to a belt conveyor and thrown on the tailings dump. Two men empty one tank in 8 hours. Water is scarce and this method is unavoidable.

The gold-zinc slimes are washed and the wash water is passed through a filter consisting of a 7 foot wooden tank with perforated bottom, over which is placed first burlap, then a cheap cotton blanket, and last a muslin bag. They are then dipped out of the boxes and thrown into a lead-lined tank, and, as they are being put in, full-strength sulphuric acid is added slowly. When all the slimes are in, the portion caught in the filter is added and the whole is diluted by one-fourth its bulk of water. Live steam is turned in and the contents are boiled until solution of the zinc is complete. This takes from 8 to 10 hours. The tank is now filled with water, allowed to settle and the solution is decated on the same filter as before used. The dried muslin bag is then placed on top of the gold precipitate and burned. The gold is drawn off from the bottom of the tank and dried. Equal parts of gold and flux are mixed in a No. 80 crucible and melted. The flux is:

	Parts by weight.
Borax	10
Bicarb. of soda	10
Potassium nitrate	¼
Silica	3

From this melt a matte and gold button result. The gold button is put in a crucible with a charge of potassim nitrate and a soft iron rod and given a second melt. A pure bar results.

The average costs of treatment of ore per ton are:

Tramming ore to mill	$0.22
Disposal of tailings	0.09
Repairs	0.02
Milling	0.14
Cyaniding	0.38
Acid treatment, fluxing and melting	0.02
Total	$0.87

Tailings run 67 to 80 cents. Therefore ore running over $1.67 can be treated.

The Iron and Coal Trades Review, April 17th, 1908—The evolution of the coal mine explosion is traced by Mr. E. J. Deason in the Iron and Coal Trades Review. After much experimenting Nobel, in 1867, found that he could control nitro-glycerine by blending it with Kieselguhr. Dynamite, or Nobel's Safety Powder, was patented on May 7th, 1867. Nobel had previously patented the detonator in July, 1864.

For some years the formula, 75 per cent. nitro-glycerine and 25 per cent. Kieselguhr, was used. This af-

terwards was known as "Dynamite No. 1." "Dynamite No. 2" was made to meet the demand for an explosive for use on coal and rocks of varying hardness. It proportions were: 18 per cent. nitro-glycerine, 71 per cent. nitrate of potash, 10 per cent. charcoal and 1 per cent. paraffin. In 1875 Nobel made the advance of including gun cotton in the list of ingredients. Other nitro-glycerine explosives were brought out by Nobel. But meanwhile, although Nobel monopolized the manufacture of this class of explosives, much attention was being paid by other investigators to the "Nitrate Class" of compounds, which class now includes the greater proportion of the powders used for coal getting.

The Explosives Act of 1875 did much to reduce accidents in the use and manufacture of explosives. But at the commencement of the last decade of the nineteenth century it became increasingly evident that further legislation was needed as regards the use of explosives in coal mines.

A new Act in 1896 brought into existence a "Permitted List." Explosives to be used in coal mines had to pass certain tests at Woolwich. The effect of the constant addition of stringent revised tests to the Act has been the elimination of all powders carrying high percentages of nitro-glycerine. The list is practically made up of the ammonium nitrate class.

Eight explosives, whose composition is given below, make up 77 per cent. of the total explosives used.

Bellite—Per cent. of total explosives used, 4.7; itrate of ammonium, 87; other constituents, per cent., 16 D. N. benzol.

Monobel—Percent. of total explosives used, 4.9; nitrate of ammonium, 80; other constituents, per cent., 10 guncotton, 10 woodmeal.

Westfalite—Per cent. of total explosives used, 5.7; nitrate of ammonium, 93; other constituents, per cent., 6 resin.

Roburite—Per cent. of total explosives used, 8.3; nitrate of ammonium, 88; other constituents, per cent., 11 D. N. benzol.

Ammonite—Per cent. of total explosives used, 8.8; nitrate of ammonum, 88; other constituents, per cent., 12 D. N.naphthaline.

Carbonite—Per cent. of total explosives used, 12.4; nitrate of potassium, 33; nitro-glycerine, 26; other constituents, per cent, 40 woodmeal.

Saxonite—Per cent. of total explosives used, 14.6; nitrate of potassium, 22; nitro-glycerine, 52; other constituents, per cent., 18 ammonium oxalate.

Bobbinite—Per cent. of total explosives used, 17.6; nitrate of potassium, 64; other contituents, per cent., 19 charcoal, 15 saltpetre.

It may thus be seen that modern practice in coal-getting is reverting to the old sulphur, charcoal and saltpetre compound. Probably, however, the safest and best method of winning coal will prove to be by the use of mechanical means.

Mining and Scientific Press, April 18th, 1908.—Mining costs in the Joplin district are written of by Doss Brittain. The low prices of spelter have reacted upon mining in this dictriet and costs are being carefully overhauled.

Royalty, in all cases calculated on the gross sale of ore, ranges from 7 to 30 per cent. If the operator is fee-owner there is no royalty.

Workmen are paid as follows:

Engineer	$2.25 to $4.25
Fireman	3.00
Hoistman	$2.50 to 2.75
Machine men	2.75
Helpers	2.25
Shovellers	$3.00 to 3.50
Powder men	3.25 to 3.50
Jig man	4.00 to 5.00
Blacksmith	2.50 to 2.75
Boss (day)	5.00
Boss (night)	3.00

The superintendent is usually paid $150 per month.

Steam, gas, and electricity are the forms of power used. The cost of one horse-power hour using steam is 1.75 cets, running non-condensing. Steam power with gas, non-condensing, costs about 0.75 cent per horse-power hour, while with gas condensing the cost is reduced to 0.5 cent. Gas power runs as cheap as 0.25 cent. Electricity costs 1.25 cents per horse-power hour.

The cost of explosives per ton of material broken should not exceed 10 to 12 cents.

Mills are insured at a rate of $2.50 to $5 per $100 valuation.

The actual cost of placing a ton of zinc concentrate in the bin is variously estimated from 50 cents to $1.50, the latter including all necessary expenses involved in a year's work, pumping, exploring, timbering, construction work, and general expense.

The operation of mining crude ore includes:

Breaking ground	$0.41
Shoveling	0.21
Hoisting	0.14
Pumping	0.10
Exploring	0.10
Timbering	0.01
Total cost of mining	$0.97
Milling	0.25
General expense	0.25
Construction	0.14.
	$1.48

Mines and Mining, April 17th, 1908.—In an editorial on the market value of copper, Mines and Mining reaches the conclusion "that in the next couple of years the selling price of copper will be from twelve to fourteen cents, and that any increase will be but temporary, due to universal causes. This is a condition we cannot avoid, since nearly all of our large producers can mine, smelt, and refine the metal at a cost of ten cents, or less, and in many cases the gold and silver contents more than pay all charges."

The Mining World, April 18th, 1908.—In this number Ralph Stokes' article on "Record Shaft Sinking on the Rand Gold Field" will appeal to the managers of metalliferous mines in Canada. Mr. Stokes speaks in high praise of "the time-honored combination of white supervision and Kaffir muscle."

Deep shaft sinking in the Rand has few drawbacks. Water troubles are almost nil and at a depth of more than 3,000 feet a full 8 hour shift can be performed without the aid of artificial ventilation, so slight is the increase of temperature with depth.

PERSONAL AND GENERAL.

Dr. A. M. Campbell, of Ottawa, was in Toronto recently.

Mr. Leon C. Jones has retired from the management of the Canada West mine, near Taber, Alberta.

Mr. J. R. Cowans, general manager of the Cumberland Coal & Railway Company, has returned to Springhill, N. S., after a visit to Quebec and Ontario.

Mr. W. J. Prisk, late of the Dominion Antimony Company, West Gore, N.S., is directing the development work of the Eagle Mining Company's property at Renfrew, N.S.

Mr. J. Dix Fraser, late works manager of the Dominion Iron & Steel Company, Sydney, N.S., has accepted the position of general manager of the Atikokan Iron Company, Port Arthur, Ont.

Mr. F. N. Flynn, for the past year manager of La Rose, Lawson, University and other mines of the Timmons-McMartin corporation at Cobalt, has resigned and will shortly return to the States.

Mr. H. Mortimer-Lamb, secretary of the Canadian Mining Institute, met the Toronto members of the Council at the King Edward Hotel on May 6th. Plans for the reception of British delegates next summer were discussed.

On April 22nd Mr. A. J. McNab, metallurgist of the Consolidated Mining & Smelting Company, Trail, B.C., was united in marriage to Miss A. Bingay at Yarmouth, N.S. Mr. and Mrs. McNab are expected to return to Trail before the end of May.

The Senate of Queen's University at the annual convocation held in Kingston, Ont., on April 29th, conferred upon Mr. Milton L. Hersey, of Montreal, the honorary degree of L.L.D. In the Senate's letter of notification the reason for granting this honor is given as being "in consideration of your position as the leading man in Canada in your chosen profession of consulting chemist and chemical engineer." Dr. Hersey, whose career was outlined in these columns recently, is now chairman-elect of the Canadian Section of the Society of Chemical Industry.

One of the first official acts of the Earl of Crewe, the newly-appointed Secretary of State for the Colonies, was to cable to Mr. Herbert C. Burchell, of Sydney, N.S., offering him the important position of Director of Public Works for Jamaica and a seat on the Executive Council there. Mr. Burchell is the vice-president and managing director of the Sydney Cement Company. He is a graduate of McGill University of long standing. He was formerly Government Engineer in New Foundland, and has made valuable reports to the Colonial Office on the resources of British Honduras. It is not often that the authorities go outside the ranks of the permanent services to find men for official positions in the Crown colonies. The offer indicates a high appreciation of Mr. Burchell's standing as a Canadian civil engineer.

LAND MADE GOOD BY ITS PEAT.

In the work of reclaiming the 25,000 acres in the great peat bogs of Konigsmoor and Marcardsmoor in the Leer District, East Friesland, the land will be drained by a network of 25 miles of canals, and a station for generating electricity will be established at the junction of the main canal with the high road from Leer to Wittmund. Current from this station will be distributed over an area 30 miles in diameter. The peat will serve as fuel, the plows and other machinery used in fitting the land for cultivation being driven by power from the bog products, which will also give light and power to many surrounding towns.

OUTLINE OF PROPOSED SUMMER EXCURSION OF THE CANADIAN MINING INSTITUTE.

The outline given below is provisional. It is subject to modification in all its details. The date of the arrival of British delegates at Quebec is, however, understood to be fixed as August 24th. The itinerary is as follows:

Stage I.—Nova Scotia and Quebec Excursion—Quebec to Sydney, including, in Nova Scotia, visits to the Pictou and Glace Bay coal mines, to the Dominion Iron and Steel Works, and the Nova Scotia Steel and Coal plant. In Quebec, the asbestos and copper regions of the Eastern Townships will be visited, Quebec to Montreal. Time required, approximately 9 days. Approximate cost, $150.

Stage II.—Ontario Excursion—Montreal to Toronto. Niagara Falls, Cobalt and Sudbury will be visited, probably also the Atikokan Iron Company's Works at Port Arthur. Time, 6 days. Cost, $100.

Stage III.—Western Excursion—North Bay to Victoria, B.C., and return, including visits to the Fernie and Bankhead coal mines, the St. Eugene silver-lead mines at Moyie, the copper-gold mines and metallurgical works of Rossland and Boundary, the Bonnington Falls power plant, etc., etc. Time required, 25 days. Approximate cost, $250.

It is roughly estimated that the cost of the whole excursion will not exceed $500, and it is hoped that these costs may be somewhat reduced if arrangements, now being negotiated, are satisfactory completed.

CORRESPONDENCE.

To the Editor,

"The Canadian Mining Journal."

Dear Sir,

In your last issue the reviewer of Mr. Low's "Technical Methods of Ore Analysis" makes an error in crediting me alone with the design of the new form of electrolytic apparatus referred to. This apparatus was designed by Mr. George A. Guess and myself after much joint experimenting.

In connection with this I would like to draw attention to the difference between Guess' method and the ordinary electrolytic method for copper. According to Low the preparation of the solution by the ordinary method calls for at least 15 separate time and attention requiring operations such as heating, filtering, and washing, and 13 addditions of reagents. Guess' method, which, by the way, is entirely independent of the style of apparatus used, calls only for boiling with nitric acid, the addition of the special nitro compound and dilution with water. The subsequent electrolysis requires a much shorter time, as stronger current densities are used. The results are as accurate as by the older method.

Guess' work in the electrolytic assaying of copper and of lead is the most important contribution to the art of assaying since the introduction of gasolene furnaces.

Yours faithfully,

H. E. T. HAULTAIN.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.

The Sydney Daily Post is offering a weekly insult to the intelligence of its readers in the shape of letters signed "Shotlighter," the object of which appears to be to discredit the present Grand Officers of the P. W. A., presumably for political motives, and to herald the golden and Saturnian age of U. M. W. A. reign, as now exemplified in the States. This gentleman begins one of his mendacious epistles as follows: "When there is lack of matter for argument it is always safe to appeal to prejudice" and thereupon proceeds to make a dreadful example of himself by writing in a strain that we venture to assert is redolent with the savour of prejudice added to an evident and abyssmal ignorance of mining that at once suggests a nigger in the woodpile.

We have nothing to do with P. W. A. or U. M. W. A., and we leave the internal arrangements of trades unionism in Cape Breton to those whom it concerns, but we do object to an attempt to upset the pleasant relations that now exist between the Dominion Coal Company and their men, and to the utterly useless and inflammatory letters which the Post is now publishing, much to its own detriment and discredit among the mining towns.

A few quotations may serve to justify our language and to show the unprejudiced wisdom of our Glace Bay Solon. Referring to the late three years' contract, he writes: "The safety lamp was introduced without any rise in wages, although by using it the miners' earning power is lessened by 'fully ten per cent.'" The single quotes are ours. This statesment needs no analysis, and it has not even the garment of plausibility to cover its indecent nakedness. If "Shotlighter" had ever seen the last sad journay of the victims of a mine explosion he would not use such mischievous and dangerous arguments. Maybe, seeing that he so loves the ways of U. M. W. A., he could view with equanimity the sight of such processions as have recently wended their doleful course in that favored land where the U. M. W. A. has its main stamping ground. The man who will appeal to the ignorant prejudice of the few and attempt to inflame the minds of men against so necessary a precaution as safety lamps is incontinently condemned out of his own mouth, and no further utterances of his are worth our attention.

However, the average man has so pathetic a faith in the truth of the printed page that we think it is necessary to point out a few more of the unbiased statement of this ingenious prevaricator.

He states that the U. M. W. A. have already secured an equitable Compensation Act and an eight hours day for miners in Western Canada "whose wages are 100 per cent. higher than ours." If this is so there are exceedingly fortunate men in Western Canada, but we saw a letter the other day from Fernie, B.C., stating that soup kitchens had been opened there to relieve the distress, and the writer (a Cape Bretonian) said he wished he were back where Canadians manage their own business, namely, in his own country. It is a little naive to say that the U. M. W. A. had obtained the two legislative measures above referred to. We presume they were passed by a Canadian legislature, and we are under the impression that they are measures not of American origin, and we have never heard that the U.M.W.A. ever obtained such measures in their own land. We admire the gall of the man who will try to tell us that we can learn anything in the way of legislation relating to mining from the United States or any labor organization from that country. We will undertake to say that we have good mining legislation in Nova Scotia, and it is enforced also, which is more than can be said of the district controlled by the U. M. W. A. politics.

"Shotlighter" states that "wages earned are from various causes falling." We admit it, everywhere but in Cape Breton. We may say that the pay roll of the Dominion Coal Company in March was the largest in its history, and further that the average wage earned per man employed was the highest on record also.

The Post writer criticises some remarks of "Rambler" in the Mining Record, and refers to this well-known person as a "wiseacre." Incidentally it occurs to us that "Rambler" has in all probability forgotten more about mining matters than "Shotlighter" ever knew, although we apologize to the former for the comparison. To quote: "According to this wiseacre we would simply be put out of business, while cheap American coals would flood Canadian markets," and other like absurdities. This reads more like an appeal to prejudice than an argument, and no attempt is made to disprove the statement referred to. Suppose P. W. A. passed, and U. M. W. A. became the order of the day, and it were thought well in the interests of 400,000 miners in the States that they should have a larger share in Canadian coal markets, would they then be so solicitous for Cape Breton? This reminds us that a writer from Springhill in criticizing some former remarks of ours in this column fell foul of the opinion expressed that Canadian should keep themselves free from the imbroglio of U. M. W. A. politics, that "wonderful game," as it is described by the Coal Trade Journal. He asked why international and artificial boundaries should be allowed to stand between the brotherhood of man, and why such boundaries were ignored in religious matters, finishing by the remark that we were living out of harmony with the designs of our Creator. This may be, but the cold and naked truth is that Canadians can not afford sentiment when dealing with the United States in matters of business. Here we are a lone seven million against seventy million on the other side of the line. Despite the Free Coal League and the altruistic balderdash that is talked by some pre fervid trades unionists, anything approaching reciprocity either in trade or in organizations must be impossible between two such unequal forces. If Canada is going to play a lone hand let her play it. And may we be preserved from the Pinkerton van, the picric acid bomb, the Gatling and the revolver, the illegal trial and the red flag of anarchy that are amongst the choice flowers of American trades unionism. We can dispense with these little amenities in Cape Breton.

Perhaps we have labored this matter too much, and have made a molehill out of a mountain. At any rate there is a very well defined feeling down here that there is no real enthusiasm behind this amalgamation talk, and that the efforts of the Post and its henchmen are directed against the personal prestige of the present leaders of the P. W. A.

To return to "Shotlighter"—he states that the workmen of the Dominion Coal Company, in accepting the recent award of the Board of Conciliation, have been "hoodwinked," that the advances given are "mythical" and that the men have been the "dupe" of their employers. We take it this is a serious reflection on the members of the recent board. Dr. Kendall and Prof. Shortt satisfied themselves that the award given meant a net gain the men of about $70,000 per annum. Did our Münchhausen ever read of the person who threw mud at the "shining one" in the Pilgrim's Progress? It would be just as well if he mixed a little truth with his statement, but we notice that whenever by chance there is a modicum of truth in "Shotlighter's" letters it is that half truth which is "ever the worst of lies."

We hope we have shown the mischievous unreliability of the correspondent of the Post and we again wish to deprecate the attempt made by a local newspaper to upset the industrial peace that means so much for Cape Breton industries, everyone of which is dependent on the coal mines. Everybody, merchants, workmen and operators, have taken fresh courage from the way in which the recent Conciliation Board arranged matters and promised unrestricted development for at least two years, and if the Post sees fit for the sake of pandering to the restless element and the sensational appetite that exists in all communities to act the part of the gratuitous firebrand, so much the worse for the Post. When they employ a "Shotlighter" they should take care that his squib is not damp. We naturally conclude that he would use a squib. We don't suppose he ever heard of a detonator.

Although at the beginning of the month conditions promised well for an early opening of St. Lawrence navigation, the ice was very heavy for the last three weeks of April, and the Dominion Coal Company's steamer fleet were tied up in the St. Lawrence for quite a time. At the time of writing, however, the ice has largely passed to the southward, and shipping will begin in earnest the first week of May. The output of the mines during April was approximately 300,000 tons. The reduction in output compared with the previous month was due to idleness of the mines enforced by lack of shipping due to ice conditions. Lifting from bank will probably commence early in May, and for some months to come the Sydney and Louisburg will have all it can handle in the way of coal.

The Hub Colliery was idle during most of the month of April for the purpose of installing a modern electrical endless haulage system, which has necessitated the straightening and widening of the Main Deep. The new man hoisting engine is completed and running. The whole mine has been cleaned up and repaired after the fire and flooding, and is now in better shape than ever before. It will be working in full operation again by the end of the first week in May.

The work on the No. 12 Branch is being pushed vigorously, and a large number of men are employed on the line. The work of building dwellings is also proceedings, and there is a quite respectable bank of coal waiting for the railway.

NEW BRUNSWICK.

St. John.

From a gold strike made on a branch of the Restigouche, interested parties believe that the future gives promise of great mineral development in that country. Early last fall a number of Campbellton gentlemen became interested in the matter, and claims were staked out and preliminary work done.

For several years the question as to the possibility of gold, copper and other minerals being embedded in the rocky hills on the banks of the Restigouche has been a subject of comment. There were many stories of the finding of gold by early settlers, but nobody seemed certain as to the locality of the find. It was a recent discovery, however, that resulted in the formation of a company several months ago.

On Friday, the 17th ult., Messrs. William S. Montgomery, Dalhousie, W. A. Mott, Maxwell M. Mowatt and George G. McKenzie, members of the company, left for Charlo and from there drove to the property, which is situated on the Upsalquitch, and inspected the mine, which was being worked by a small force with a view to learning the exact extent of the vein of ore. The party returned from their trip on the following Monday, all well satisfied with the results so far obtained. The hill was being tunnelled and the ore taken out was improving considerably at every shot. It was also reported by members of the party that work was well under way on the shaft.

The company have secured rights over some five miles of country, and it is expected that "pay dirt" will be found in sufficient quantity to warrant the construction of a branch line from the mine to the Intercolonial Railway, some fifty miles distant.

It is said that several other companies have been formed and prospecting is in progress all over this section of the country. Some have been successful and further reports are looked for in the near future.

From Bathurst comes the report that T. M. Burns has received from Mr. Drummond a communication in which he speaks favorably of the Gloucester iron deposits.

In his letter, Mr. Drummond states that it is the intention of his company to open up the mines this summer.

The Provincial Government will be approached relative to certain concessions and rights to control the great water power of the Nepisguit River. Mr. Drummond adds that he considers the Gloucester iron deposits among the finest in the Dominion. It is Mr. Drummond's intention to visit Bathurst in the near future, when it will be learned just what the intention is with regard to smelting, etc.

A company was formed some three or four years ago, when a charter was obtained permitting the construction of a railroad from Bathurst to the Twin Tree mine, which received its name from a freak of nature in the form of two magnificent pine trees with but one top, and standing just behind the camp. Efforts are now being made to alter the charter in some respects, after which the company will proceed to carry out the plans for which it was organized.

ONTARIO.

"66." A correspondent, writing under date of April 18th, sends us some details concerning the new mining camp south of Lorrain. The camp is styled "66"—a name that has stuck. Its location is approximately 16 miles southeast of Cobalt, Ont., on the Ontario side of Lake Temiskaming, in the unsurveyed country south of Lorrain. The district was not thrown open to prospectors until late in 1906. The country is heavily timbered, the clay soil is deep, and there are few outcrops. Hence prospecting has been slow. In the latter part of the summer of 1907 discoveries, however, were made. The Keeley, Landon, Mayhow-Brough, Maiden, Forniri and other claims have excellent showings.

From the Keeley claim, 350 sacks of ore, reported to average 3,000 ounces of silver per ton, were taken out along the vein by three men since December, 1907. At a point six feet from the surface the vein is from 4 to 6 inches wide and is largely composed of wire silver. The Haileybury Silver Mining Company are sacking a high grade cobalt ore. Their main shaft is sunk to a depth of 40 feet on the vein. Very little development will put several other properties in a position to make small shipments of high grade ore. The veins in the Maiden and Forniri properties lies in the slate, cutting through the contact with the diabase.

The field explored for two miles south of the Keeley claims to the shores of Lake Temiskaming northeast, has shown native silver or cobalt in encouraging quantity.

The district is accessible by good trails and lumber roads. Lumber companies are still operating. Transportation by steamer on Lake Temiskaming is offered either from Mattawa or Haileybury Wharf and storage facilities are to be provided by the transportation companies, and the Ontario Government will extend aid in buildinga wagon road from the wharves to the mining sections.

Cobalt.

Southeast Coleman.—The discovery of a rich vein at 200 feet in the Temiskaming property, a feeder from the main vein, the increasing richness of the new vein on the Badger and the location by a diamond drill of a promising vein on the Shamrock, has resulted in increased activity in the development of properties in this section. On the Shamrock, which lies directly north of the Beaver and east of the Badger, diamond drilling was started some weks ago. The first drill hole was put down at an angle of 45 degrees to cut the contact of the Keewatin and diabase in the southern part of this lot. At 110 feet a number of small veins were encountered, and for 20 feet the ground was much broken and cut with narrow stringers. Small silver values were obtained from every core taken out. At 120 feet a 12 inch vein of calcite showing native silver and assaying 690 ounces was cut. The drill, which is now down 170 feet, will be sunk at least 100 feet more. A shaft will be started at once on the vein. The shaft on the new vein of the Badger is down 125 feet. Drifting has been started at 106 feet. The vein is 5 to 7 inches wide and carries silver. The development work in this section of the camp has demonstrated that a depth of 75 to 100 feet must be reached before high silver values are encountered. The Beaver No. 1 shaft, now down 85 feet, will be sunk 100 feet deeper. The vein, which is now practically solid smaltite and niccolite, carries small silver values. On both the Lumsden and Coleman Development properties, shafts will be sunk 100 feet and drifting and crosscutting done at this level. Negotiations are now under way to arrange for the resumption of work on the Rochester and the Davis properties.

Silver Queen.—The new 12 drill compressor and 100 horsepower boiler are now installed. It is announced that diamond drilling has proven values to a depth of 390 feet, and the No. 1 shaft will be sunk to a depth of 400 feet.

Chambers-Ferland.—Two shafts are being sunk here, and one is now down 16 feet and the other 32 feet. Contracts have been let for the sinking of both. Hoists will be put in at both shafts and machine drills used. Air for hoists and drills will be obtained from the Nipissing. No. 1 shaft has a vein of calcite and smaltite, and No. 2 a 4 inch vein that will run six thousand ounces.

Buffalo.—A very rich vein has been struck here. The ore is similar to that on the Crown Reserve.

Right of Way.—Cheques for the payment of a seven per cent. dividend have been sent out. In 15 months $105,000 has been paid in dividends, making a total of 21 per cent. The original price of the property was $50,000.

Silver Leaf.—From October 21, 1907, to April 8, 1908, the ore mined amounted to 312,144 pounds, worth $150,000.

City of Cobalt.—On May 5 a new vein was encountered 80 feet from the shaft at the 137 foot level. The vein is from 3 to 4 inches wide and as rich as any yet found on the property.

Thethewey.—In the week ending May 2 the Trethewey shipped three cars of ore, weighing 192,800 pounds. The total output since January 1 is 679,916 pounds, making this mine fifth in the list of shippers. Reports from the mine indicate that the property is in excellent shape.

Night Hawk Lake.

On Gold Island, in Night Hawk Lake, there is a three stamp mill in operation. The ore being run through is taken out by quarrying and is showing high values. The ice on the lake is still firm.

Montreal River District.

On Monday, May 11, the Ontario Navigation Company will begin the operation of a line of steamers from Latchford to Elk City. The gasolene boats will also start regular trips on this date. A large quantity of supplies and mine equipment which has been accumulating at Latchford, awaiting the opening of navigation, will be sent in as fast as the boats can handle the stuff. A number of engineers and representatives of Canadian, English and American capital are booked for the first boats.

ALBERTA.

Coleman.

Trade still continues dull all over the Province, but the Coleman mines of the International Coal and Coke Company are working almost full time. The coal trade in the Crow's Nest Pass depends to a great extent on railroad consumption, and owing to the decrease of traffic the demand for coal has been small. The past mild winter has also been against the coal trade.

It is claimed that about 2,000 men are idle around the various mines.

Edmonton.

A Winnipeg and St. Paul development company have secured an extensive coal area near the Pensluna river, north of this city. These holdings were taken up last fall and the prospecting work done shows the area to be valuable. No steps will be taken at present, however, as it is impossible to do much development work without railway facilities.

Canmore.

A serious accident occurred in the mines of the H. W. McNeil Company, whereby three men were killed and three men slightly injured. The names of the killed are Mathew Sarri, gangwayman, Gus Capleson, bratticeman, and Wm. Willmot, fire boss. The cause of the accident was an explosion of gas in the Carey vein. This vein gives off a lot of gas and only safety lamps are used. It appears that some time ago owing to the gaseous nature of the coal the Mine Inspector ordered that nothing but flameless explosives be used in this vein. In complying with this order the company obtained a supply of a safety explosive known as Negro Powder and gave strict orders to their shotlighters that nothing but Negro Powder was to be used for blasting the coal.

At the inquest on the victims of the explosion it was demonstrated that the explosion followed almost immediately after a shot had been fired in the main gangway, and that the shot hole had been charged with "Giant" instead of "Negro Powder."

It was the shotlighter's (Mr. Willmot) duty to see that only "Negro Powder" was used, but he had evidently allowed the miner to use "Giant" instead, with fatal results.

(Editor's Note.—This is an instance of the gross lack of a sense of responsibility on the part of workmen. Such cases are of more frequent occurrence than is supposed. In the above case the company had issued specific instructions that none but flameless powder should be used in the mine. The mine was known to be gaseous. Why a miner should wish to disregard orders and risk the lives of his comrades and himself, is not apparent. The lesson is a painful one. But it must not be lost. Flameless powder, and safety lamps, are absolutely necessary for the prevention of coal mine explosions. One criminally careless workman can in one moment render useless all precautionary measures instituted by a responsible management.)

SASKATCHEWAN.

Taylorton.

The Board of Arbitration which has been appointed under the Lemieux Act to deal with the labor troubles of the Western

Dominion Collieries of Taylorton met in Winnipeg. The chairman of the board was Judge Myers, while Frank Sherman represented the men, and J. Hannah represented the operators.

The chief points in dispute between the Coal Company and the men are—recognition of the union, wages scale, an eight-hour bank to bank day, employment of check weighmen, price of miners' supplies, and reinstatement of local union officers who have been discharged.

BRITISH COLUMBIA.

Rossland.

Mining is still looking busy in Rossland district. At the big producers development work is being kept well advanced and new ore bodies are daily being opened up and blocked out. While some of the mines could ship more ore, average shipments only will be maintained while copper demains at its present low price, as the managers can see no good in working out the mines and not getting a good price for their product, which is reasonable.

The hills surrounding the camp are being more thoroughly prospected at the present time than they ever were in the boom days, for the simple reason that the miners staked anything in those days, as there was a sale for any kind of wild-cat, but to-day the prospectors seems to know that a barren ledge is of little value to him and the ground now being staked in the South Belt in nearly all cases has a mineral showing of some little promise. Quite a number of the old abandoned claims have been sampled and restaked and where they are still held by the mining companies if there is any promising ore in sight overtures have been or are being made to the companies with a view to their being leased by ambitious miners.

The lessees of the Mayflower are taking out ore and the men on the Nest Egg have uncovered a body of copper ore. The Red Eagle has joined the shipping list, having sent a car of hand-picked ore to the smelter at Trail. They are still working and taking out good grade ore on the Blue Bird. The ore is at present being stored in the Homestake bins and will be shipped as soon as the rails are laid on the Homestake siding, but it is the intention of the Blue Bird management to have a siding and ore bins put on Blue Bird ground before very long. L. Carter, of Spokane, president of the company, states that his company will take over the mine and push development work immediately upon the expiration of the present lease, December sixth next. The ledge still retains its strong appearance and the prospects are good for the future. Of course the rock in this vicinity is much broken up and misplaced and the Blue Bird people can expect more or less trouble with their ledge at depth, but from its present appearance it looks as though it would continue downward in good form.

The Trail smelter has entered into a contract with the Snowstorm Mining Company, of Idaho, to treat 100 tons of ore from their mine per day, and the ore is now being received at the smelter. This ore carries over four per cent. copper. Mr. W. H. Aldridge, managing director of the Consolidated Company, in commenting upon the affairs of his company, states that the Centre Star, War Eagle and St. Eugene mines are all looking well at depth and that the smelter at Trail is working successfully and is one of the company's most valuable assets. The company has 1,150 men on its pay roll at Rossland, Trail and Moyie. Good progress is being made at Hosmer, where the C. P. R. is opening up their 4,000 acres of coal land. The 20 coal coal seams which are being opened up by means of two 2,800 foot tunnels have six or eight first-class workable seams among them. The 240 coke ovens are being rushed along as fast as possible. The total plant and equipment will cost over $1,500,000.

Shipments from Rossland for the week ended April 25th amounted to 5,065 tons.

Phoenix.

Work is going along nicely at the Granby mines, and while the shipments are not as heavy as they were during March, yet they are much greater than they were during the same month in either 1906 or 1907, and this despite the fact that one furnace is cold most of the time, in consequence of repairs being made. The furnaces will be connected up with the new dust chamber and gone over one at a time, so as to not restrict the output to too great an extent.

During the week ended May 2nd the Phoenix mines shipped 19,942 tons of ore down to the smelter, and that plant treated 22,005 tons. This gives 354,872 tons mined and 348,229 tons of copper-gold ore smelted during the year to above date. At the present moment No. 3 furnace is out of commission.

Diamond drill exploration has been resumed in the mines and will be continued during the life of a contract recently entered into with Boyles Bros. On the 400 foot level there is now in successful operation a method of self-dumping cars which was devised by the local manager, Mr. A. B. W. Hodges, and which is expected to reduce the cost of handling ore on that level. The cars, which are loaded by gravity in the stopes, are brought to the chutes by electric locomotives and by means of a wheel attached to the cars engaging in an incline track the big five tone cars are dumped while in motion and in a few seconds.

Work is to be resumed on the Joe Joe in the near future. The Tip Top is the only electrically equipped high grade property that is doing any work at the present moment in this district.

Nelson.

At a recent meeting of the Ymir Mines in London the hope was again advanced that the ore body now being sought at depth would be located in the due course of active development work and the directors were urged to assist all they could in the raising of funds to go ahead with this work. Diamond drilling is now in progress on the property. A rich strike is reported from the Gallagher mine in the Ainsworth district. The ore body, a soft iron carbonate, carrying gold and silver, is three feet thick. This ledge is all good sacking ore. The mine has produced considerable ore during the past six months, and there are now two carloads of ore all sacked and ready for transportation to the cars as soon as the trail will permit of hauling.

One cannot but admire the pertinacity of F. Griffiths the owner of the Westmount claim that is now shipping high grade silver ore. Mr. Griffiths, who has always had great faith in the Westmount, began its development over ten years ago. Being unable and somewhat unwilling to interest capital, he alone and unassisted drove a 1,000 foot adit and was successful in cutting the Westmount ledge where he knew it ought to show up. Often for as long as three months at a time he worked away in the wild, rugged hills without hearing the sound of a human voice or feeling the warm handclasp of a fellow-being. He is certainly made of the best material that goes into the make-up of a pioneer and deserves the reward that he is at present reaping. The last car of ore sent from the Westmount to Trail smelter averaged 405 ounces of silver per ton.

A new company has been organized to take over the affairs of the Lucky Boy, Trout Lake, and will be operated by them.

Work in the Sheep Creek district continues to show good results. On the Devlin Group, now being developed by a syndicate of Nelson men, the ore body is showing up strong. The ledge is of quartz, 6 feet in width, carrying free gold to the extent of $15 per ton. On the hanging wall there is a particularly rich pay streak about one foot wide, which will average $100 per ton in gold. Steady operation is the slogan of the management at the Queen mine, and they are now busy in

stalling their new compressor, hoist and other machinery. The Kootenay Belle, Mother Lode, Nugget and other Sheep Creek properties are showing up well.

Sixty men are now employed at the Silver Cup mine in the Lardeau. Geo. Alexander is acting as manager for the English interests, which now control the property. The Cup last month shipped 160 tons, the largest shipment in the history of the mine. The ore averaged 150 ounces silver, ¾ ounce gold and 40 per cent. lead. The 160 tons above mentioned were valued at $18,000. The mine is to be further developed by a long tunnel, which will be started fully 400 feet lower down the hill than any existing adit.

GENERAL MINING NEWS

NOVA SCOTIA.

Londonderry.—Messrs. T. J. and J. J. Drummond and Mr. Edgar MacDougall, all of Montreal, accompanied by Sir James Heath and Mr. Hamilton Benn, of England, visited Londonderry on April 30th. Two days were spent in inspecting the property of the Londonderry Iron and Mining Company. The East and West mines were examined, and the blast furnaec plant. A visit also was paid to the company's saw mill at Folly Lake.

Halifax.—Examinations for the purpose of granting certificates to managers, underground managers and overmen, under the Coal Mines Regulation Act, R. S., C. 8, S. 1, may be held somewhat earlier this year than last. The date, however, will shortly be announced. The board for the purpose of granting them certificates is made up as follows: Cape Breton District—Henry Mitchell, Dominion; A. B. McGillivray, Glace Bay; Isaac Greenwell, Sydney. Cumberland District—Joseph Moss, Springhill; Henry McArthur, River Herbert; Amos Billereau, Joggins. Pictou District—John Rigson, Stellarton; Charles J. Core, Stellarton; W. W. Gray, Westville. Inverness District—M. S. Beaton, Inverness; J. W. Johnston, Mabou; Robert D. Anderson, Halifax.

The Dartmouth Ferry Commission have accepted the offer of the Inverness Coal Company for the supply of 5,000 tons of coal of 2,240 pounds. The company offered No. 1 slack at $2.15 per ton, to be delivered at Commissioners' wharf, delivery to commence 1st May or sooner if required; to be delivered in schooners, steamers or barges of 800 tons capacity, free over ship's rail; weight as per scales. They also offered 1,000 tons run of mine at $3.40 per ton. This is the lowest offer for a number of years. The Gowrie Company offered coal at $2.50 per ton. The Mabou Coal Company's offer was for $2.65 per ton, weight to be taken as bill of lading, delivery at commence about 15th May or on opening of navigation, and completed 15 December. They also certified coal against spontaneous combuction.

Port Hood.—The miners of the Port Hood-Richmond Railway-Coal Company stopped work on May 1st. Not one word of warning was given the management. Evidently the men thought that the time was opportune. The summer's output of coal has been sold in advance, and a continued strike would embarrass the company seriously.

The miners struck for a 15 per cent. increase on the general labor pay roll and for 5 cents a ton increase on coal cutting. They gave no indication of their intention and the management was taken entirely by surprise. On May 5th the men resumed work. A conciliation board is to be appointed.

QUEBEC.

Montreal.—On May 1st there were seven Dominion Coal boats in Montreal. Thirty-four thousand four hundred and sixty-four tons of coal were being unloaded. On April 30th 6,355 tons were unloaded at Quebec.

To encourage research work in the study of the structure of metals, etc., arrangements have now been made to offer a scholarship at McGill University. The particulars are as follows:

The holder shall be preferably a graduate of the metallurgical engineering course. The appointment will not necessarily be limited to one year, provided funds are available. The student will receive in the first place a salary of $500 per year, and from $100 to $200 per year will be available for defraying the cost of supplies and apparatus.

The object of the research will be to ascertain the effect of the structure of metals (as revealed by the microscope) on their mechanical properties and their wearing quality; particularly in the case of steel rails, axles, tires and chilled iron wheels.

Provision will be made for enabling the holder of this scholarship to visit certain steel works and rolling mills, so as to learn the effect of mechanical treatment during the process of manufacture.

The student holding this post will be expected to assist in the laboratory teaching as far as it relates to the special work on which he is engaged.

The student would be termed Research Fellow in Metallurgical Engineering.

For the first year the necessary funds have been promised by Mr. Milton L. Hersey, M.A. Sc., who has already contributed an annual prize to students in the metallurgical course at McGill.

The work will be caried on under the direction of Dr. A. Stansfield, the professor of metallurgy, who, for a number of years, has made a special study of the heat treatment of steel and the nature of steel rails.

ONTARIO.

Belleville.—The Deloro works of the Deloro Mining and Reduction Company are operating continuously, almost up to capacity, on Cobalt ores. One hundred and fifty men are on the pay roll. Additions to the plant are proposed. Weekly shipments of bullion are now being made. In the first week of May fifty-one ingots were shipped to London. The total weight was 2,2550 pounds.

From the Henderson talc mine, near Madoc, large shipments will soon be made. A mill for grinding this superior talc is to be installed.

The Silver Leaf Mine, Cobalt, has shipped one car of high grade ore to the Deloro smelter. The arsenic plant, running in conjunction with the smelter, is producing arsenic regularly. The stamp mill is in commission on a test lot of gold arsenic ore from the Lawson-Pearce mine, near Marmora.

Cobalt.—The discovery of a new vein on the Temiskaming 200 foot level, is creating a sensation. The vein contains 8 inches of silver. A new find on the Buffalo is also reported.

By the accidental explosion of dynamite two men were killed at La Rose mine on May 4th. The men were working on the second level. They were found about 1 o'clock. One of them, a Galician, was dead. The other, Leonard, a Frenchman, died shortly after being taken out of the mine. It is stated that both men were inexperienced.

ALBERTA.

Frank.—The Bellevue mines, belonging to the Lille Collieries, have resumed work. Thirty miners are employed.

The Frank coal mine of the C. A. C. Company was inspected on April 29th. Inspector Heathcote found it in good condition. It has been closed for three months.

BRITISH COLUMBIA.

Fernie.—On January 1st, 1909, the agreement between the C. P. R. and the Crow's Nest Pas Coal Company will expire. By the terms of this agreement the C. P. R. was prohibited from engaging in coal mining in the Crow's Nest district. Preparations are now being made at Hosmer, where the C. P. R. owns 4,000 acres of coal lands, to erect plant and houses. One million five hundred thousand dollars will be expended. Five hundred men are now employed in opening up. Two cross-cut tunnels, each 2,800 feet long, are being driven to intersect twenty seams of coal, six of which are good, workable seams. In these tunnels a system of compressed air haulage will be installed. Commenced next January shipments of coal will be increased until an output of 3,000 tons per day is reached. During the summer 240 coke ovens will be completed. For shipping the coke a new type of steel coke car is to be introduced. Each car will have a capacity of forty tons as compared with the wooden box cars, which only hold twenty-two tons. The C. P. R. also owns forty square miles of coal lands on the Elk river, forty miles north of Michel, in the Crow's Nest district.

Mr. W. H. Aldridge, managing director of the Canadian Consolidated Mining and Smelting Company, is acting as chief consulting engineer on behalf of the railway company.

Phoenix.—The first fatal accident in many months took place on Sunday, 26th April, at the Granby Mines. Two men fell from the bench on which they were working in Stope No. 61, on the 300 foot level, on to a muck pile 25 feet below. Both men were probably killed instantly. The bodies were not discovered until some time after the accident.

Revelstoke.—For fourteen years the Silver Cup mine has produced ore steadily. It employs 50 to 75 men. Last year a new compressor, operated by water power, was installed. The Silver Cup ore averages 150 ounces of silver, ¾ ounce of gold and 40 per cent. lead per ton. In March it shipped $18,000 worth of clean ore.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

A Glasgow syndicate has leased nearly 300 acres of peat land in Bowness-on-Solway in North Cumberland. The peat will be subject to special treatment for manufacturing and other purposes.

The wages of coal miners in Cumberland have been reduced 2½ per cent.

A thick seam of coal has been struck at a workable depth on Thorne Moor, Yorkshire, proving the existence of coal over a stretch of ten miles of country between Bentley and Thorne.

FRANCE.

The tin deposits at Montebras, in the department of La Creuse, are to be developed by Anglo-French company, known as the French Mining Syndicate, capitalized at £250,000. Some of the tin occurs in a white feldspathic rock which yields as a by-product a fine quality of china clay.

PORTUGAL.

A gold mine of exceptional richness is reported to have been discovered in Northern Portugal, and a great rush to the district has set in. Auriferous quartz veins have long been known to occur in that region, especially in the Provinces of Minho and Traz-os-Montes, lying north of the Dowro.

NORWAY.

The production of iron ore in 1907 showed a large increase, the output last year being 130,000 tons, against 80,000 in 1906. Of the year's product, 90,000 tons were exported, in the form of ore, while 40,000 tons were treated by magnetic separation and briquetted.

The copper mining industry during 1907 made much progress. Existing mines largely increased their output, and a number of new enterprises wer started. The Sulitelna mines were the heaviest producers, and of their output 11,900 tons of copper pyrites were treated on the spot, yielding 701 tons of nearly pure copper.

AUSTRALASIA.

The Mount Lyell Mining and Railway Company has just installed at its reduction works, Queenstown, Tasmania, two large turbo-blowing engines, which with the smaller one which has been in use for a year will make the finest blowing plant in Australasia. The practice in pyritic smelting at the works is advancing.

An official report on the Wolfram deposits near Marysville, Victoria, states that this mineral has been found over a tract of country said to be two miles square. A wide field is presented for further prospecting, as it is by no means certain that either the best alluvial or the best lode Wolfram has yet been found.

The prospects of the tin-dredging industry in Northeastern Tasmania are encouraging. The Dorset bucket dredging plant in the Ringarooma valley is handling between 12,000 and 14,000 cubic yards of ground per week and other plants are making a fair turnover.

In boring for coal at Cape Ford, Northern Australia, a depth of 1,459 feet has been reached. Several small seams of coaly matter have been cut and, indications being considered favorable, a more powerful plant is to be employed.

SOUTH AFRICA.

Several large amalgamations of mining companies have taken place or are in progress. The most important of these which is now under consideration by the companies affected, is that of the East Rand Propietary Mines, which will absorb several other enterprises embracing a total of 2,801 claims. It is estimated that the amalgamation will effect a reduction in working costs amounting to 1 shilling per ton.

A lode has been struck in the City Deep shaft on the Rand at a depth of 2,865 feet, showing good assay values across a 42 inch working face. This result is regarded as highly encouraging in regard to the future of the Rand mining industry.

The gold production of Rhodesia for the first three months of 1908 was 147,141 crude acounces, as against 134,417 ounces for the corresponding months of last year.

UNITED STATES.

The Montana Mine Owners' Association has secured control of the smelter of the Idaho Smelting and Refining Company at Ponderay, Idaho, which has been closed since last fall, and will increase the capacity of the plant from 250 tons to 1,000 tons per day, giving employment to about 300 men. It is proposed to spend $100,000 on improvements and the plant will be equipped for treating copper, a refinery being added. The name of the operating company will be the Montana and Idaho Smelting Company.

Oil and gas have been discovered near Colorado Springs, Colorado, and a company capitalized at $1,000,000 has been organized to develop the field. They have secured control of about 6,500 acres.

It is proposed to substitute cement pillars for mine timbers in a number of Leadville, Col., mines. A series of experiments has been arranged for and should cement prove satisfactory it will be largely adopted.

The sum of $195,000 has been appropriated by the American Congress to be used by the Geological Survey in studying means for lessening the number of mine accidents.

Company Reports.

INTERNATIONAL COAL COMPANY.

Dividends Paid in 1907 Aggregate 5½ Per Cent.

The annual report of the International Coal and Coke Company, Limited, operating collieries at Coleman, Alta., has just been issued. It is signed by A. C. Flumerfelt, the president, and runs as follows:

The net profits for the year, after paying all operating expenses at head office and mine, amount to $251,049.21 (being 8.9 per cent. on the outstanding capital), which sum has been derived from the various departments of the company's business, together with the sale of coal and coke, receipts on account of lots sold from the company's townsite and returns from water and electric light supplied by the company to the people of Coleman.

On the 1st of February, 1907, a dividend of 1 per cent. on the capital stock of the company was paid; a similar one on the 1st of May, which was increased to 1½ per cent. on the 1st of August and 2 per cent. on the 1st of November, making in all 5½ per cent., aggregating $154,000, and as you will see by reference to the balance sheet on the opposite page, the handsome sum of $97,049.21 was carried to surplus account for the year.

Coal produced—for the year under review—was 372,480 tons, of which 61,998 tons were sent to the company's ovens and produced 39,121 tons of coke, all of which found a ready sale, the balance being marked as coal.

The total amount of the pay roll for 1907 was $437,723.19; average number of men employed, 465; days worked, 236; the average tonnage being 1575. During the year there were some additions made to the plant (expenditure under this head being $45,943.57), which included coke ovens, additions to haulage plant, a Bradford breaker, snow sheds and a thoroughly well-equipped wash house for the men, all of which were deemed necessary in the company's interests and approved by the board.

STATISTICS AND RETURNS.

The output for the month of April at the collieries of the Nova Scotia Steel and Coal Company is about the same as that for the month of March. Number 4 colliery is just beginning to produce coal again, and allowing for two days of which the mines were idle the general output will be about the same as preceding month.

Following are the figures:

	Tons.
No. 1	71,612
No. 3	2.,760
No. 4	576
No. 5	7,261
Total	55,212

The coal shipments of the Novo Scotia Steel Company for the three months were as follows:

	Tons.
Shipments March, 1908	28,757
Shipments March, 1907	21,854
Increase March, 1908	6,903
Shipments 3 months, 1908	117,737
Shipments 3 months, 1907	86,829
Total 3 months, 1908	30,908

The Crow's Nest Pass Coal Company, Limited, report the output of the collieries for the week ending May 8th as 17,453 tons, a daily average of 2,909 tons.

The output of the Crow's Nest Pass collieries for the week ending May 1 was 18,826 tons, or a daily average of 3,137 tons.

SMELTER RECEIPTS.

	Week.	Year.
Granby	19,905	334,530
Consolidated	4,726	88,002
Le Roi	371	24,806
Other mines	.....	1,511
Total	371	26,317

The total receipts at the various smelters for the past week were 25,002 tons, and for the year to date 454,579 tons.

Manager Levy cabled the London office of the Le Roi Two Mining Company the following report of the operations of the Josie and Vancouver for the month of March: "Josie Mine report for last month—shipped 2,440 tons. The net receipts are $52,947, being payment for 3,275 tons shipped, and $2,293, being payment for 151 tons of concentrates shipped. In all $55,240. Vancouver mine report for last month: Shipped 50 tons. The net receipts are $4,423, being payment for 60 tons shipped, and $1,024, being deferred payment for 121 tons concentrates. In all $5,447. No lead concentrates shipped."

Shipments from the Springhill Collieries of the Cumberland Railway and Coal Company amounted to 33,457 tons for the month of April.

BRITISH COLUMBIA SHIPMENTS.

Following are the shipments for the week ending April 25 and year to date:

Boundary shipments—

Mine.	Week.	Year.
Granby	19,905	334,530
Other mines		462
Total	19,905	334,992

Rossland shipments—

Centre Star	3,242	55,040
Le Roi	371	24,806
Le Roi No. 2	114	10,325
Other mines	.....	500
Total	2,727	90,671

Slocan-Kootenay shipments—

St. Eugene	233	8,332
Whitewater	23	445
Whitewater, milled	280	4,620
Poorman, milled	250	3,350
Queen, milled	185	2,950
Second Relief, milled	145	1,520
North Star	139	1,004
Standard	86	532
Rambler-Cariboo	22	457
Ruby	43	141
Milly Mack	102	128
True Fissure	18	50
Other mines	.....	13,352
Total	1,526	36,748

For the first four months of the year the Dominion Coal Company's output is 237,580 tons ahead of the corresponding period last year. The figures are as follows:

	1908. Tons.	1907. Tons.
January	314,108	252,348
February	285,649	225,588
March	346,529	212,931
April	298,745	316,384
	1,245,031	1,007,151

DOMINION COAL OUTPUT FOR APRIL.

	Tons.
No. 1	48,000
No. 2	58,721
No. 3	32,279
No. 4	38,528
No. 5	42,757
No. 6	20,453
No. 7	713
No. 8	18,072
No. 9	27,948
No. 10	12,979
	300,450

The following report of the operations of the Le Roi mine for March was cabled to the London office of the company: "Shipped from the mine to Northport during the past month 6,700 tons, containing 2,680 ounces gold, 4,600 ounces silver, 170,000 pounds copper. Expenditure on development work during the month, $7,250."

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp and those from January 1st to date:

	Week end April 25.	Since Jan. 1.
Crown Reserve	40,000	40,000
Cobalt Central	10,600	107,180
La Rose	292,200	1,729,452
McKinley	61,000	1,063,000
Nipissing	101,170	1,044,600
Silver Queen	44,000	524,000
Silver Leaf	70,800	132,800

The total shipments for the week were 680,170 pounds, or 340 tons.

It will be noticed that the Crown Reserve mine has joined the list of shippers.

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:

	Week end May 2.	Since Jan. 1.
Buffalo	.....	517,520
Coniagas	.....	380,910
Cobalt Lake	.....	180,610
Crown Reserve	.....	40,000
Cobalt Central	.....	107,180
City of Cobalt	110,520	338,600
Drummond	.....	92,340
Foster	.....	168,600
Kerr Lake	.....	330,710
King Edward	.....	127,240
La Rose	132,200	1,861,652
McKinley	60,900	1,123,900
Nipissing	64,030	1,108,630
Nova Scotia	.....	120,790
Nancy Helen	.....	140,420
O'Brien	126,980	1,635,570
Right of Way	.....	60,120
Provincial	.....	143,210
Standard	.....	39,730
Silver Queen	.....	524,200
Silver Cliff	.....	52,000
Silver Leaf	.....	132,800
Townsite	.....	85,100
Temiskaming and H. B.	.....	539,000
Temiskaming	.....	237,250
Trethewey	192,800	679,916
Watts	.....	114,430

The total shipments for the week were 687,430 pounds, or 343 tons. The total shipments from January 1 to date are 10,882,918 pounds, or 5441 tons.

The shipments for the month of April practically tripled those of 1907, when 533.15 tons of ore were shipped out from the camp. For April, 1908, the shipments were 49 cars and a total of 2,634,240 pounds. These shipments for the month of April are particularly notable in view of the fact that since April, 1907, several large concentrating plants have been installed

in the camp, and while the number of ounces of silver will be increased thereby, a large shipping tonnage will be cut off in consequence.

The shipments from the camp for the month ending April 30 are as follows:

	Cars.	Pounds.
Mc-Kinley-Darragh	7	366,240
Provincal	2	93,210
Nipissing	5	224,430
O'Brien	4	251,250
Buffalo	2	107,980
La Rose	15	854,200
Temiskaming and H. B.	2	121,000
Kerr Lake	1	60,330
Nova Scotia	1	40,000
Cobalt Central	2	57,480
Crown Reserve	1	40,000
Silver Queen	1	44,000
Silver Leaf	1	70,800
Trethewey	3	192,800
City of Cobalt	2	110,520
Total	49	2,634,240

The shipments for the first four months of the current year are much heavier than those of the same period for 1907.

Fifteen mines shipped 1,317.55 tons in April, 1908. The shipments for April, 1907, only amounted to 535.15 tons. Cobalt shipped nearly three times as much in April, 1908, as it did in April, 1907.

Jan.	Feb.	March.	April.	Total.
1325.89	1173.80	1832.79	1317.53	5650.01
980.11	903.71	1027.59	533.15	3444.56

Increase in tons for first four months, 2205.45.

The above increase is the more remarkable owing to the fact that many shipping mines that formerly sent second grade ore to the smelter now ship concentrates.

Another consideration is the high standing for the first four months of 1908 of the new shippers.

The Watts, Temiskaming and Hudson Bay, Temiskaming, City of Cobalt, Silver Leaf, Provincial, Nova Scotia and Nancy Helen now rank among the camp's most regular shippers.

The shipments for week ending April 25th went to the following smelters: La Rose to Denver; Nipissing to U. S. Metal and Refining Company, Carteret, N. J.; Crown Reserve, to Ledoux and Company, New York; Silver Queen to Copper Cliff; Silver Leaf to Deloro; McKinley-Darragh to Pennsylvania Smelting Company, Carnegie, Pa.; Cobalt Central to Rickett and Banks, Waverly, N. J.

The Transvaal gold output in April, as officially reported in London, was 565,832 ounces, fine, a decrease of 9,069 ounces from the output of March. The April output last year was 537,019 fine ounces; in 1906, 439,243. Value of the April output, calculated on the basis of the above estimate, compares as follows:

April, 1908	$11,924,000
March, 1908	12,210,000
February, 1908	11,510,000
January, 1908	11,900,000
December, 1907	12,393,000
April, 1907	11,405,000
April, 1906	9,329,000
April, 1905	8,477,000
April, 1904	6,497,000
April, 1903	4,839,000

MARKET REPORTS.

Coke.

May 8th—Connellsville coke, f.o.b. ovens—

Furnace coke, prompt, $1.55 to $1.65.
Foundry coke, prompt, $2.10 to $2.25.

Pige Iron.

May 8th, Pittsburg—

No. 2 foundry, $15.40 to $15.65.
Bessemer, $16.90 to $17.15.
Basic, $16.15 to $16.40.
Malleable, $16.90 to $17.15.
Southern No. 2, $16.40 to $16.90.

Other Metals.

Tin, Straits, 30.55 cents.
Copper, prime lake, 12.75 to 12.85 cents.
Lake, arsenical brands, 12.70 to 12.80 cents.
Electrolytic copper, 12.70 to 12.85 cents.
Sheet copper, 17 cents.
Copper wire, 14.75 cents.
Lead, 4.20 cents.
Spelter, 4.67½ cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.65 to 8.70 cents.
Aluminium, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $23.50 to $26 per ton.
Bismuth, $1.75 per pound.
Quicksilver, $45 per 75 pound flask.

May 9	52¼	24 1-16

Silver.—The U. S. Mint has made no purchases of silver for the past four weeks. The consumption, at present, of the world, is far behind the production. India has not been a buyer for some time. China has been selling silver abroad. Since the first of the year England has shipped to India about 50 per cent. of the amount going out on the corresponding period of last year, or £2,310,438, against £4,409,784.

Amatite ROOFING

IF you had a sample of Amatite in your hand you would see in an instant why it needs no painting or coating to keep it waterproof.

It has a rough surface of *real mineral matter* on the weather side. It is evident to anyone that it is no more necessary to paint such a surface than it is necessary to paint a stone wall. Stone needs no paint; neither does Amatite. It is strong enough in itself to bear the brunt of rain and wind and sun without a protective coat of paint.

To paint Amatite would be a waste of time and trouble.

Amatite will last for many years without any care whatever. It is made to be *trouble proof* as well as *weather proof.*

A roofing that consists of smooth materials, made to receive a heavy coating of paint, is not a roofing at all—the paint is the real roof.

If you are told that certain roofings don't need painting when first laid, don't be deceived into thinking that they are like Amatite. The first coat of paint has been applied at the factory—that's all, and it will wear off in a little while and require renewal.

No paint is good enough to make a durable roof; a thick layer of pitch, faced with a real mineral surface, is far better—*and that means Amatite.*

MINERALS And How They Occur

A Book for Secondary Schools and Prospectors

BY

WILLET G. MILLER

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, now in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How They Occur" can be obtained from the Canadian Mining Journal

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

The Latest Book on the Electric Furnace

Electric Smelting is a subject of increasing importance to Canadian Engineers and this work contains a clear and connected account of the principle on which electric furnaces are constructed, the uses to which they can be put and the more important details of their construction. The articles upon which the book is based appeared in the Canadian Engineer during 1906.

The Electric Furnace

Its Evolution, Theory and Practice

By Alfred Stansfield, D. Sc., A.R.S.M.

Professor of Metallurgy, McGill University

208 Pages. Fully Illustrated. Price $2.00.

The evolution of the Electric Furnace from its simplest beginning is as briefly set forth as is consistent with clearness, together with the important facts relaring to its theory and practice.

The rapid growth of the Electric Furnace makes it increasingly difficult for the metallurgist to keep in touch with its recent developments. A few years ago it was a scientific curiosity, but now it threatens to rival the Bessemer converter, the open-hearth steel furnace, and even the blast furnace itself.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

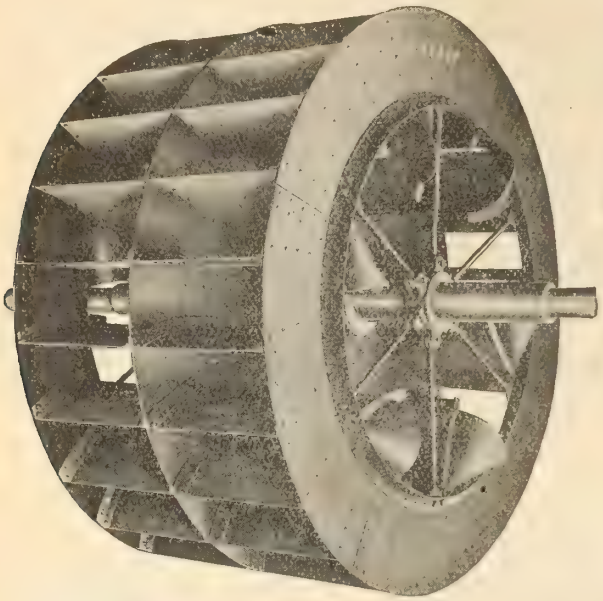
Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work, by reason of their high air efficiency, substantial design, and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)



SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.

ONTARIO MINING ADMINISTRATION AND POLITICS.

We have watched, with some degree of concern, the course taken by the partizan press of Ontario in criticising and defending the administration of mining law in this province. The organs of both parties have gone to regrettable lengths in misstatements and palpable untruths.

It has remained, however, for the Toronto Globe to cap the climax of recklessness. In its issue of May 22, in an editorial entitled "Government Claim-Jumping," it gives utterance to an unqualified condemnation of the mining policy of the Provincial Government. The editorial will inevitably affect public confidence in the mining industry. That it is inspired by political agitators and that its writer has either been an ignorant dupe, or has deliberately closed his eyes to the truth, are facts that he who runs may read. In any case the "Canadian Mining Journal" is called upon to correct the malicious untruths and half-truths thus put in circulation.

Firstly, it is germane to our subject to remark that it would become the Globe to maintain a discreet silence on topics pertaining to mines and mining. In fact it has little right to pose as the champion of right. Last year, when the mining fever was at its height, the Globe, despite full information as to the character of the projects it was aiding and abetting, continued to publish the most flagrant specimens of wild-cat advertisements. In this respect, in view of the Globe's actual standing and the rarified moral atmosphere in which it moves and has its being it was more offensive than its worst contemporaries. Only one Toronto daily chose the path of decency and honour—and that one was not the Globe. As between tainted money and serving the true interests of the people, the Globe chose the former alternative. So much for the past.

Early in June an election is to take place. To the "Canadian Mining Journal" there is neither politics nor party. Hence, so long as the industry which it represents is not injured, the "Canadian Mining Journal" has no concern in the battle. But when, in the course of an election campaign, a newspaper attacks the very foundation of that industry, in its intemperate desire to discredit the work of a department, it is high time for us to speak.

The Globe states that the excuse made for "Government claim-jumping" is that the "discoveries were not made when the patents were obtained." In what sense this can be called an excuse we cannot see. Under

the present Mines Act discovery is essential. If the Government inspectors are not shown satisfactory evidence of discovery they are in duty bound to throw out the claim. This is an integral part of the Mines Act. Its operation has entailed hardships. It is by no means a perfect law. But it is law and is accepted and must be lived up to.

That the Mines Act is perfect is not claimed even by those who framed it. That the administration of the Department of Mines has been flawless is not to be urged for a moment.

On the other hand we speak whereof we know when we say that the inspectors, upon whose shoulders falls the onus of carrying out the letter of law, are straightgoing, carefully selected, professional men. For the benefit of the Globe we may add that these inspectors are chosen with absolutely no reference to politics. This is a rare and valuable feature and has an important bearing upon the administration of the law. Indeed it goes far towards rectifying manifest imperfections in present legislation.

The last few years have witnessed an expansion in the mineral industries of Ontario, for which the discovery of Cobalt is not wholly responsible. And the Bureau of Mines has done notable work before and since that epoch-marking discovery. Ontario does not lose by comparison with any other province of the Dominion. Let its Department of Mines be measured by these standards, and not by the criminally irresponsible abuse of the Globe.

There is in the far west a weekly that makes no pretensions to piety. Its humor is unconventional, possibly a trifle mediaeval. Often its columns are frankly objectionable. We need not make the comparison more invidious by giving the name of this knight-errant of journalism. But we may be allowed to express an open preference for the outspoken honesty of the western sheet as opposed to the unscrupulous, bitter, and deplorable partisanship of the psittaceous Globe.

SLOCAN ZINC ORES.

It is reported that, after long deliberation, the Supreme Court of the United States has reversed the decision of the Board of Appraisers in regard to the dutiability of zinc sulphide. This will end the interminable discussion as to the interpretation of the word "calamine." Whilst the appraisers were technically right in objecting to the classification of zinc sulphide as calamine, yet the logic of the situation demanded equal rights for either the carbonate, the silicate or the sulphide of the metal. Therefore the 20 per cent. ad valorem duty on zinc ores entering the United States from Canada is no longer to be collected.

From the Slocan zinc concentrates have been shipped as far as Wales. The United States smelters, however, have been the principal purchasers, and it was at the instance of the latter that the present question of duty was taken up and settled.

The difficulty has not been without incidental benefit. The Canadian smelter, now about to commence operation near Nelson, will aid in the development of the Slocan, especially in the case of small shippers. The removal of the ad valorem charge will encourage competition.

TWENTY YEARS' PROGRESS IN SOUTH AFRICA.

The recently elected president of the Institution of Mining and Metallurgy, Mr. Alfred James, in his inaugural address summarized the advances and improvements in the methods of mining and milling South African gold ores. Mr. James entered upon his first professional engagement in South Africa twenty years ago. His review covers the intervening period.

Twenty years ago the metallurgy of gold received but scant attention. Technical papers on the subject were rare. Practice generally was crude and mining and milling methods were largely rough and ready. In South Africa operators were confronted with the problem of extracting the gold from heaps of tailings assaying in places as much as 1 ounce per ton.

The advent of American mining engineers not only brought about an era of elaborate and expensive installations, but induced a spirit of eager competition that reacted beneficially upon all concerned. It is noteworthy that the best of the British engineers have more than held their own ground.

Amongst other evidences of change and improvement it may be noted that in 1888 comparatively few gold mines employed assayers. To-day the metallurgist is supreme. But success was gradual. The first filter presses were failures. Now they are an acknowledged necessity. Like instances are not wanting.

Mr. James sums up, as worthy of notice, the following improvements in mining and milling:

> The sorting of waste rock from reef matter to be milled.
>
> The use of separate crushing stations containing high capacity crushers.
>
> The general adoption of mechanical transport for the ore from the mine to the mill.
>
> The provision of bins of great storage capacity to provide against breakdown in mine or hoisting engine.
>
> The provision of special water supply—usually with its acidity neutralized—for the mill.
>
> The use of heavy stamps. In place of 850 pound stamps and a per diem output of 1½ to 2¼ tons per stamp, 1,500 pounds to 2,000 pound stamps with a capacity of 6 to 10 tons per stamp are not uncommon.

The use of long, unbroken silvered plates for mill amalgamation, and of shaking plates for forced amalgamation, after tube mills. At Waihi the plates are installed in a separate building.

The adoption of regrinding appliances. The cost of tube milling African sands is now reduced to 5½d. per ton re-ground. It is doubtful, however, whether tube mills are more economical in running than stamps for increas- output, as the consumption of power is high.

The provision of automatic weighing and sampling devices.

The introduction of the cyanide process for recovering gold from sands and slimes.

The use of improved mechanical roasting furnaces.

The provision of tailings wheels for elevating pulp. These are probably to be superseded by three-throw pumps of the type used for filter pressing.

The practical effect of these improvements may be measured by the fact that ores, formerly looked upon as impossible of commercial treatment, are now considered profitable. Thus ore containing 6 dwt. of gold per ton is now mined and milled at a good profit, and large plants have been erected to treat sand carrying less than 1½ dwt. of gold per ton and slime assaying only ½ dwt.

In concluding his thoughtful address, Mr. James makes a strong plea for the standardization of mine accounts. We heartily endorse this request. The need is universal.

HIGH GRADING.

In our last issue we made brief reference to the prevalence of "high grading" in Cobalt.

Circumstances have since arisen that make strong comment necessary.

On May 12th a Cobalt jeweller was arrested in Toronto. He had in his possession ore to the value of about eight hundred dollars. When questioned by his captors the man informed them that graft of this sort was so universal in Cobalt that he felt obliged to secure a share. The answer is naive. Also it is significant.

The Mine Owners' Association employed the detectives that captured this particular theif. Apparently the Association is the only active deterrent influence.

But why should not the workmen take it upon themselves to aid in suppressing this systematic looting? Would it not be wiser and better for the miners to indulge in some honest efforts to remove the blot of "high grading"? If the labor leaders were as active in their opposition to wrongdoing of this sort as they are in fomenting useless strife, there would be far fewer grievances and far less unnecessary friction.

A thief is defined in the dictionaries as one who deprives another of property secretly. Inadequate as this definition is, it serves the purpose well enough.

Judged by the moral standards nominally accepted in social life, many of our successful financiers, promoters and politicians are thieves. Occasionally a member of one of these classes oversteps the legal boundaries of right and wrong and is caught. Mostly, however, their operations are within the law, or cleverly evasive of the law.

In the learned professions there is no pronounced tendency to misappropriation. A doctor, an engineer or a lawyer loses caste if he is suspected of carelessness in handling the property of others. The commercial and industrial classes of Canada are as clean-handed as those of any other country in the world.

What are usually termed the laboring classes are not looked upon as displaying marked evidence of dishonest propensities. On the contrary, it is popularly believed that the honest toiler is the salt of the earth, and some varieties of modern socialism (much misused name!) inculcate the dogma that none but the laborer is honest at all.

Possibly in no calling is there such need of intelligence and resourcefulness as in mining. The good miner is, to our mind, one of the best types of producer. His work is not specialized to such an extent as obtains in modern manufacturing establishments. Neither is it beset with more dangers. But the dangers and the requirements are such as encourage a sense of personal responsibility. Initiative, adaptability and quickness of perception are developed in the efficient miner.

We repeat that, as a class, miners rank high in our social economy.

It is, therefore, much to be deplored that the dishonesty and greed of a number of Cobalt miners has brought dishonor upon an entire community, and particularly upon the workmen of that community.

And it should at once be recognized as an imperative duty on the part of every honest miner that he do his utmost to bring to justice each and every culprit. A pronouncement to this effect from the representatives of the labor organizations would be timely. The stigma should and must be removed and the workmen themselves can act most efficaciously.

JOURNALISTIC AMENITIES.

The Sydney Record recently paid this "Journal" the compliment of reproducing from its correspondence columns some remarks on the question raised by the appointment of the Eight Hours Day Commission in Nova Scotia, and in doing so it prefaced the extract by stating that the Glace Bay cor-

respondent of "The Canadian Mining Journal" "reflects the views of the Dominion Coal Company." This statement has been made by the Record previously, and we wish to be allowed to correct any false impressions that may arise if we permit it to go unchallenged.

The Glace Bay correspondent of this "Journal" reflects the views of no person but himself. These letters are, however, written from Glace Bay. Everything that emanates from Glace Bay must of necessity bear the impress of Dominion Coal, and while to one person this may be synonomous with the mark of the Beast, yet to another person it may suggest nothing beyond the operations of a business machine on whose efficient operation the welfare of some 30,000 persons directly depends. Everybody in Glace Bay is either the servant of the Coal Company, or the servant of the servants of the Coal Company. Correspondence from Glace Bay to an organ of the mining industry must have an inevitable tinge, but apart from this we plead not guilty to the Record's impeachment.

A corporation is not an entity, but an aggregation of parts. It is a commercial machine, ingeniously assembled and designed for one purpose only, namely, that of earning dividends on the moneys entrusted to it by the shareholders. A corporation may have a policy, and usually has a very well defined one, but it cannot hold any views, for that is the privilege of the individual. We take it that if the Dominion Coal Company were anxious to impress upon the public the rectitude of their policy they would not seek to do so through the medium of an anonymous correspondent to a technical journal that is read largely by a class whose policy is at one with that of the Dominion Coal Company. They have other and more telling means of publicity, and while we cannot but feel flattered at the Record's evidently high opinion of our perspicacity in this matter, we must make it very clear that our views are uninspired and original. Whatever bias we have is purely personal.

PREPARATIONS.

Arrangements are now completed with the Commissioners of the Canadian National Exhibition, to be held in Toronto from August 29th to September 14th, whereby a day is to be set apart for the mining industry. Ample space has been allotted for mineral and metallurgical exhibits. The Provinces are to be asked to aid in making a strong and impressive display. Mining corporations are also expected to contribute towards the success of this praiseworthy plan.

Manufacturers of mining machinery and supplies are particularly requested to spare no effort to make a fine showing.

September 4th is the day selected as "Miners' Day." On this day the British and European delegates, visiting Canada under the auspices of the Canadian Mining Institute, are to be in Toronto. Their presence will lend additional importance to the event.

Dr. J. O. Orr, the secretary of the Exhibition Commission, whose office is in the City Hall, Toronto, will give all information on request.

DR. ROBERT BELL.

It is reported that Dr. Robert Bell, Chief Geologist of the Survey Department, will soon be granted leave of absence for a number of months, to be followed by superannuation at the maximum rate. Dr. Bell has seen many years of continuous service. He is still vigorous and energetic and will, no doubt, continue his excellent professional labors unofficially. "The Canadian Mining Journal" wishes to extend the hope that Dr. Bell's well-deserved release from the burden of routine will be a period of profit and pleasure to himself and to his friends.

MINING IN THE PROVINCE OF QUEBEC FOR YEAR 1907

Mr. Obalski's annual report contains the usual summary of mining operations. The calendar year 1907 is covered by the report. We have already given a detailed list of the production of minerals. The increase over 1906, as noted before, is $371,370. We shall now take up the more important branches of the industry in the order followed in the report.

Iron.

The Canada Iron Furnace Company at Radnor, and the John McDougall Company at Drummondville, using mostly bog ore, produced a total of 10,047 short tons of charcoal iron. There was no important work done on the other iron deposits of the province.

Masses of hematite, occurring irregularly in a strip of ferriginous dolomite, in Dunham Township, County of Missisquoi, were examined. Picked samples showed 69.49 per cent metallic iron.

Magnetic and titanic iron ore was found in the Seigniory of Rigaud Vaudreuil, Beace.

Referring to the magnetic sands of the north shore, Mr. Obalski claims that they can be profitably concentrated into a product yielding 67 to 70 per cent. metallic iron, about 1 per cent. titanium and practically no sulphur or phosphorus. The applicability of the Grondal process is pointed out.

In the neighborhood of Three Rivers and at St. Malo, ochre is mined and calcined by three operations, the Canadian Paint Company, the Champlain Oxide Company, and S. W. Argall. Calcined ochre is shipped to Canadian and United States consumers. Some crude ochre also is shipped. For 1907 the output of crude was 2,700 short tons, worth $5,400; of calcined, 2,300 tons, worth $29,530. The work continued only throughout a portion of the year. Sventy-five men were employed.

Chrome Iron Ore.

Three companies worked the chrome iron ore deposits in the Township of Colraine—the Black Lake Chrome & Asbestos Company, the American Chrome Company, and the Canadian Chrome Company. A total of 40 stamps and 12 Wilfley tables make up the mill equipment of these companies. Seventy-six men are employed during periods of from 4 to 11 months. The output for the year was 5,721 long tons of 1st and 2nd class ore and concentrates valued at $63,130. A considerable amount of diamond drilling is being carried on.

Copper.

The mines in the Capelton region were regularly worked by the Nichols Chemical Company, and the Eustis Mining Company.

At the latter's mine a depth of 2,800 feet has been reached. Electric power is supplied from a waterfall two miles from the mine on the Coaticook river. Concentration works capable of turning out 200 tons of concentrate per 24 hours are installed near the railway. The equipment consists of 4 Blake crushers, 3 double rolls, and 8 Wilfley tables. The ore body in sight is large and variable in grade.

At the Nichols Company's Albert mine work was continued in Shaft No. 1. Sulphuric, nitric and hydrochloric acids and glauber salts are manufactured at the company's chemical works.

Several small promising prospects are being developed by other parties. Prospecting is being actively followed near Sherbrooke.

In the copper industry 250 men were employed. Twenty-six thousand four hundred and five long tons of copper ore were mined, valued at $160,455.

Gold.

The excitement produced by the discovery of gold in the Gilbert river in 1863 led to no important results, although an estimate places the amount of gold taken out between 1863 and 1878 as $2,000,000. Operations were then confined to a strip two miles long. Mr. Obalski urges the systematc prospecting of the district.

Near the close of 1906 auriferous quartz was found in the Township of Marstin. Assays by Dr. Milton L. Hersey showed from traces up to $10 per ton of gold. This is the first discovery of gold in quartz in apparently commercial quantity.

Asbestos.

The asbestos industry continued to flourish during the past year. The utilization of short fibres in the manufacture of boards has encouraged the opening of new mines, especially in East Broughton. Most of the companies used electric power furnished by the Shawinigan Water Power Company and the St. Francis Water Power Company.

At Thetford the King asbestos mine, the Bell mine, the Johnson mine and the Beaver mine are working regularly. At Black Lake the American Asbestos Company has acquired the mines of the Montreal & Glasgow Asbestos Company and of the Manhattan Asbestos Company, and now operates four independent mines. Other companies are the Johnson Company and the Standard Asbestos Company.

In Broughton, Colraine and Wolfestown Townships there is activity in asbestos mining. The Asbestos & Asbestic Company continue to employ about 400 in their mine and mills. Their power is partly supplied by the Shawinigan Water & Power Company. Their old quarry is 200 feet deep and is served by 18 cable derricks.

Of 1st class (crude), 2nd class (crude), fibre and paper stock the province produced 61,85 tons valued at $2,455,919. Asbestic was produced to the amount of 29,193 tons worth $27,292. Men employed, 2,141. Wages paid, $931,061.

Amber Mica.

The amber mica industry prospered during the year. Shipments increased and prices were good, especially for small mica. But towards the end of the year the demand suddenly ceased and the Ottawa trimming establishments were temporarily closed.

The Blackburn Company, working the Perkins Mill, was the most important producer. They also shipped a couple of hundred tons of phosphate.

Production of province—

	Pounds	Value
Total thumb trimmed	542,290	$197,739
Split	7,957	2,109
Rough called mica, 150 short tons, ...		24,030

Employees.—288.

Wages.—$108,600.

No white mica was mined during 1907.

Phosphate.

As mentioned above, phosphate was mined with mica in the Ottawa region by the Blackburn Brothers. This firm shiped 200 tons of 80 per cent. and 60 tons of 60 per cent. The Capelton Chemical and Fertilizer Company of Buckingham, used 35 tons of phosphate, and the Electric Reduction Company of the same place used 300 tons.

The total value of the phosphate, 408 short tons, was $3,410. Both companies named above imported phosphate from Ontario and the United States.

Graphite.

Much prospecting was done in Buckingham, Grenville, and Labelle districts. In the Buckingham region the Diamond Graphite Company, an American company, worked lots 12, 13 and 14 of range X and erected a mill on the property. The dry process of concentration is followed.

The Bell mine, operating lots 1, 2, and 3 of range V, Buckingham, took out a fair amount of ore. A mill is being erected.

The Buckingham Graphite Company, with mines and mill on lot 19 B, of range VIII, of Buckingham, did not work during 1907. A quantity of the previous year's products was shipped. Brumell's process is used here.

These were the only operating companies in Buckingham.

In the district of Grenville, and in the townships of Amherst, and Joly, there was some work done.

From the province 120 short tons of prepared graphite were shipped, valued at $5,000.

Natural Gas.

The Canadian Gas and Oil Company, whose office is in Three Rivers, sank a number of wells near Louisville, Yamachiche, and St. Barnabé. In thirteen of these gas was encountered in merchantable quantities. Gas was generally struck at a depth of 225 to 300 feet. The

bore-holes passed through clay, fine sand, and gravel before striking solid rock and gas. The producing wells are cased and connected with a distributing line. Pipe lines are laid to supply St. Barnabé, Yamachiche, and Louisville, and a 8-inch pipe line, 13 miles long, is laid to Three Rivers. The city pressure is reduced to 4 ounces.

The gas is clean and non-sulphurous. The supply is limited and deeper boring will have to be done to find more lasting reservoirs.

The report concludes with a list of companies operating in Quebec. Appended are reports of explorations north of Pontiac and on the surveyed townships of Lake Temiscamingue.

MINING IN THE EASTERN TOWNSHIPS OF QUEBEC.

By Fritz Cirkel, Mining Engineer, Montreal.

Mining in the Eastern Townships of the Province of Quebec is destined to play an important part in the mineral history of the Dominion, judging from the efforts which have been made for quite a number of years to increase gradually the capacities of the established mines or to open up new mines and add facilities for handling the output.

Asbestos and chrome iron are at present the staple articles of production; but there are other ores such as those of iron, copper, and last but not least, gold, to which little attention has been paid, and it is to be hoped that before long, earnest efforts will be made to test and exploit these deposits.

Copper deposits occur in a number of localities through the counties of Megantic, Leeds and elsewhere, the only copper mines being the Eustis and Nichols mines at Capelton, while some work was also done last year at the Ascott, Suffield and King mines. About

The 500-ton plant of the Dominion Mines Asbestos Co. and the Asbestos Plant of the Standard Asbestos Co., at Black Lake, P.Q.

32,000 tons of ore were produced of which about 8,000 tons were treated at Capelton for sulphuric acid and matte by the Nichols Chemical Company, which according to Mr. Obalski produced 374 tons of matte containing as an average 53 per cent. copper.

Considerable excitement has been caused by the discovery of gold in the vicinity of Lake Megantic, and it is reported that practically the whole territory, especially to the east of the lake, has been staked. The gold is reported to occur in quartz veins which yield in some cases satisfactory returns when assayed. However, no mining to speak of has been done, and it remains to be seen whether the mode of occurrence warrants the exploitation of the deposits on a large scale.

The asbestos industry forges ahead as usual, and, while it must be admitted that the recent financial depression has had its effect upon this market for some months past and has delayed the proper development of several new enterprises, still the outlook is most encouraging. Especially is this the case as regards the sale of fibre used in asbestos roofing slate, and asbestos board, an invention of importance in the construction of fireproof buildings. All the mines, some of which had closed down during the winter as usual, commence to gather in their full quota of men in order to resume operations. Mine labor, which at this time a year ago was scarce, seems to be plentiful, and there is now no difficulty of manning the mines and mills to their full capacity. In addition to the established mines at Thetford and Black-Lake, quite a number of new mines are opened up, especially in the East-Broughton district. This region has attracted considerable attention for some time past on account of the excellent fibre the mines produce. Careful exploration work carried on for the last two years has demonstrated that the productive serpentine belt has a far greater extent than at first supposed. The belt has not only been traced from Range 3 at East-Broughton up to Range 11 at Broughton, a total length of approximately 7 miles. but in almost every range work has been done to prove the productive character of the rock. Strange to say the serpentine occupies all lots, more or less, numbered "13" and the sinuosities of the boundaries of this belt with only one exception keep within the southern and northern limits of these lots. The following table will show the succession of outcrops and mines along the belt:

Lot 13, range 4; the Millar outcrops.
Lot 13, W.range 5; the Boston Asbestos Company, (mill under construction).
Lot 13, E. range 6; The Frontenac Asbestos Mining Company, (mill under construction).
Lot 13, W. range 6; The Quebec Asbestos Company, (in operation).
Lot 13, W.W. range 6; The Eastern Townships Asbestos Company, (in operation).
Lot 13, E. range 7; The Broughton Asbestos Fibre Company, (in operation).
Lot 13, W. range 7; The Tanguay Outcrops.
Lot 14, range 7; The Fraser mine, (not in operation).
Lot 13, range 8; The Taschereau and Bolduc Asbestos outcrops.
Lot 13, range 9; Outcrops of fibrous serpentine discovered.
Lot 13, range 10; Outcrops of fibrous serpentine discovered.

The "Boston Asbestos Company" operating on Lot 13, W. range 5, is at present constructing a mill for the treatment of about 250 tons of asbestos rock; this mill will be ready about the first of August; steam power

will be used, but it is the intention to replace this by electric power, if reasonable terms can be obtained from the electric power companies that intend to enter the field. The mill building is located at a distance of 500 feet from the asbestos outcrops, close to the track of the Quebec Central Railway; its size is 50 x 150; it will contain two cyclones and all modern appliances for the extraction of the asbestos fibre. Mr. A. A. Nor-

The new 500-ton Asbestos Separation Plant of the Dominion Mines Asbestos Co. at Black Lake, P.Q.

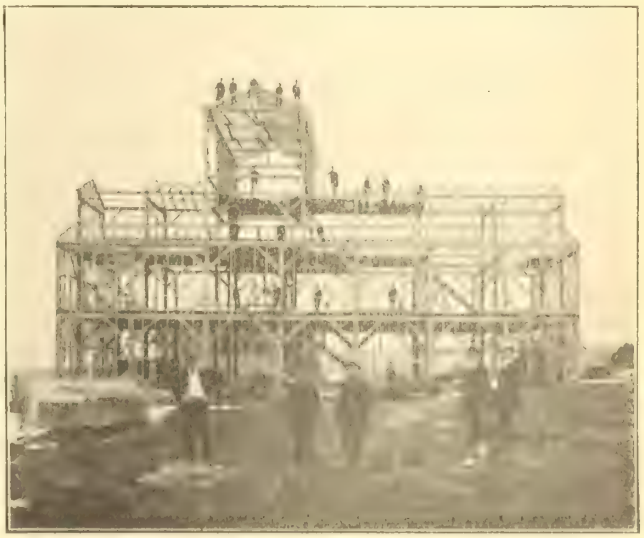
mandin of Boston is the general manager of this company. The area of the property is 85 acres.

Adjacent to the "Boston Asbestos Company's" property to the west, the "Frontenac Asbestos Mining Company," which controls an area of over 100 acres, is building a mill of a capacity of 300 tons ped day. The outcrops of fibrous serpentine, which are scattered all over the northwestern part of this property, apparently indicate that the productive fibrous serpentine covers a larger area than was originally supposed. Mr. H. Riehle, formerly of the "Union Asbestos Company," is the designer of the mill and is the manager of the company.

The "Quebec Asbestos Company" operating to the west of the "Frontenac," have been working during the winter with about 40 men, and are putting on a larger force of men with the advent of the summer season.

The "Eastern Townships Asbestos Company," which commenced to operate this mill last fall, has just been starting up again, after a shut down of about three months, due to repairs and alterations in the mill. The latter has been built during the summer season of 1907, inside six months, a rare accomplishment indeed considering the difficulties in transportation in that part of the country. Mr. P. Angers, N. P. of Quebec, is the energetic manager of this promising concern.

The "Broughton Asbestos Fibre Company" on lot 13, E. range 7, commenced operations in mine and mill in the middle of April, after a shut-down for about four months. This company, which was the first one in the district to prove the value of these peculiar ore deposits, have been operating their new mill during last year with great success; about 300 tons of rock were handled in the mill per day, producing approximately a carload or as an average about 25 tons of asbestos fibre per day. It may be said here that the success of this undertaking which at first had to surmount a great many difficulties, in in a large measure due to the untiring efforts of Co.. Williams, the manager of the concern.



Further to the northwest from these properties, excellent outcrops can be noticed on the "Tanguay," and further west again on the "Taschereau" lot. Plans of a mill for this latter promising property for the treatment of about 300 tons of rock per day are being made, and all preparations are under way to begin work as soon as the snow disappears.

At Black Lake, the big 500-ton mill of the "Dominion Asbestos Company," is almost completed, and it is expected that this company will soon bring its products, which on account of some innovations in the mill system, are said to be of superior quality, on the market. The Greenshields asbestos property, forming part of the holdings of the "Black Lake Chrome & Asbestos Company" has been sold recently to Quebec parties, and a mill is to be constructed during the course of next summer.

The Johnson Asbestos Company, the pioneer company of the district, commenced operations in 1878. Its new 500 ton mill is now almost completed. Four mills are now run by the same company.

If all the mines and mills are built and developed as contemplated at present, there will be in the beginning of 1909 altogether 7 new establishments in operation, which will add to the present mill capacity of the district approximately 2,000 tons of asbestos mill rock per day, which at an extraction of 8 p.c., would yield an additional output of asbestos of about 180 tons. The total output of the districts for 1907, according to the statistics furnished by the "Mines Branch," amounted to 62,000 tons of a value of $2,482,984.

In the chrome iron industry the output will be considerably increased in the near future, owing to the completion of the new inclined shaft No. 1, of the "Black Lake Chrome & Asbestos Company." Large bodies of crude ore have been tapped through this new shaft, which has a depth of 320 feet, delivering from 30 to 40 tons daily of high class ore, beside a good deal of milling material. From present signs it appears that

New Mill of the Boston Asbestos Co. at East Broughton.

in this industry, great activity will be displayed during the coming summer season, as the inclemency of the weather during the past winter has had the effect of reducing the regular production. There are three operating companies in the field with a milling strength of 75 stamps. The production for 1907 amounted to 7,196 tons valued at $72,901.

REPORT OF THE FRENCH STATE COMMISSION ON THE COURRIERES EXPLOSION OF THE 10TH MARCH, 1906.

(Translated from the German: "Gluckauf," 15th February, 1908.)

The following report of the Commission appointed to enquire into the Courrieres explosion has been published by the Minister of Mines:—

The cause of the initial explosion which produced the main catastrophe has not been clearly ascertained, in spite of continuous and exact researches. It has been shown, however, that its wide extension over the whole of the underground workings of pits Nos. 2, 3 and 4-11, an area of three kilometres by one and one half kilometres, was due to a coal dust explosion, produced by a combination of circumstances.

Everything points to the origin of the first explosion in the Lecoeuvre Heading, but this cannot be stated with any greater certainty than the cause of its origin. Whether it was due to a sudden outbreak of gas, or to an explosion of powder, or to whatever cause, can only be surmised.

Under these circumstances no real connection has been found for which the coal company could be held responsible between the explosion and the use of open lights in the Lecoeuvre Heading, nor of the explosive Favier I, in the place of the prescribed "safety" explosive.

Also it is evinced by all signs that the fire in the Cecile seam had nothing whatever to do with the disaster. The importance of this fire has been extraordinarily overrated. All necessary measures for fighting this fire had been taken by the company, and there was no necessity to prohibit the descent of the workmen.

In this matter no particular blame attaches to anyone.

Several circumstances may have helped to make the catastrophe a severe one, in particular the underground connection between Nos. 2, 3 and 4-11 shafts, and the imperfection of the ventilation through an irregular splitting of the air and the failure of the ventilation doors in the main roads.

The great extent of the explosion was only rendered possible by the communication that existed between the three shafts.

The number of men who died by suffocation would doubtless have been lessened if the air current had been stronger and the ventilation so arranged that it would have restored itself after the explosion and carried off the deadly gases. Instead of this, the ventilating current was completely disordered by the destruction of the numerous trapdoors and the ventilating partition in shaft No. 3. But these fatal errors were not disclosed until the explosion drew attention to them.

As the workings at Courrieres were free from gas, it seemed unnecessary to divide the mine into limited districts or to regulate the ventilation, and in general, the communication between the various shafts appeared to be justified on the ground of safety, especially as affording a way of escape to those employed underground in the case of an inrush of water.

Referring to the coal dust danger, it had not been previously supposed that a coal dust explosion of such magnitude was possible. The only cases of coal dust explosion that have taken place previously in France have not extended for a greater distance than 80 to 100 metres; with the exception of the Decize explosion, which extended over 180 metres.

However deficient the layout of the mine may appear to-day in the light of experience, yet before the explosion the need for improvement did not appear. The decision of the authorities that the circumstances did not call for a prosecution is based on an appreciation of this fact.

The disaster of Courrieres has shown unmistakably, however, that under conditions which are not yet fully understood a non-gassy mine where coal dust is present may present the same dangers as a fiery mine.

Therefore we think it is necessary from now on to extend to all coal mines the regulations for safety that govern fiery mines at the present time. Where the dust is of such a nature that it will not readily explode and the danger is thereby minimised, these regulations may be modified.

Regarding the general layout of collieries in the future, we think more regard must be had to the effective separation of the several shafts of a single colliery, with an isolation of the districts of the mine and their ventilating currents, and a limitation of their extent in order to minimize as far as possible the effects of an explosion by confining it to the smallest possible area. In accordance with the Report of the Commission on Mine Gases in November, 1906, this separation should be effected by means of iron doors, which will open outwards only, and will withstand a pressure of up to five kilograms per square centimetre, and which can be closed from either side. Finally, more attention must be devoted to a methodical system of splitting the air current to assure that every point shall receive its quota of the ventilation.

In the future ventilation partitions shall be avoided, and the exhaustion of the seam shall not be forced unless it is accompanied by the presence of sufficient material to pack the goaf.

The use of open lights is forbidden in all the mines, and only permitted explosives with approved ignition apparatus are to be allowed.

The whole of these measures are to be effective in the coal mines of the Nord and Pas de Calais Basins. Steps will be taken to put them into effect in every coal mine in France.

The provision of breathing apparatus for rescue work is prescribed by the order of 15th April, 1907. The outstanding questions therefore are the dangers of coal dust explosions and the necessary safeguards to be adopted, together with the question of the use of so called safety explosives in fiery or dusty mines.

It was demonstrated by the recent explosion in the Saar district (Prussia) and also at Courrieres itself that appreciably long portions of roadway will, if sufficiently damp, tend to hinder the spread of an explosion. It is not, however, certain that the dampness produced by sprinkling will always serve to prevent the extension of an explosion.

It has further been shown that the operation of sprinkling at short intervals is more or less useless, for the reason that the evaporation set up by the air current will nullify the effect of the sprinkling in from two to three hours.

On the other hand, it has been proved at Courrieres, and especially in the thin seams, that where the system of working tends to bring down a certain amount of

roof shale and stone, and that where the mine dust consisted of an admixture of shale and coal dust, the explosion was not carried along. It would therefore suggest itself that an admixture of shale dust with coal dust or with some inert material may lessen the danger of explosion.

Before, however, any compulsory measures of this nature are promulgated, such as the sprinkling of more or less extensive roadawys, the utility of which is not yet placed beyond doubt, and which certainly is accompanied by difficulties and numerous disadvantages, it appears very necessary to give these questions a searching investigation.

Great care is needed in the matter of so called "safety" explosives, not only as regards the strength of the charge, but also with reference to the composition of the explosive itself, on which at the present time there are two directly opposite opinions. One view is that the resultant fumes of a detonated explosive should contain no combustible gases in order that they shall not pollute the atmosphere, nor increase its proportion of dangerous constituents. The other view is that an explosive should contain none of those gases that will aid combustion, as oxygen for example, as these gases by increasing the temperature of detonation, increase the danger of exploding a mixture of gas and coal dust.

It is therefore necessary to establish by an investigation what are the safest and at the same time the most useful explosives.

As the other recommendations are already or shortly will be the subject of new regulations, we consider that the Commission on Mine Cases, who have already studied the dangers of coal dust and the question of explosives, should be directed to undertake the work of investigation, to conduct the necessary experiments, and to publish their findings, not only as refers to sprnikling, but also in relation to the general recommendations that have preceded. Further, we recommend that as soon as possible they issue their report on the work they have already done in connection with explosives; but regulations governing the size of charges and the strength of explosives now in use, shall at once put into effect without waiting for the recommendations of this Commission.

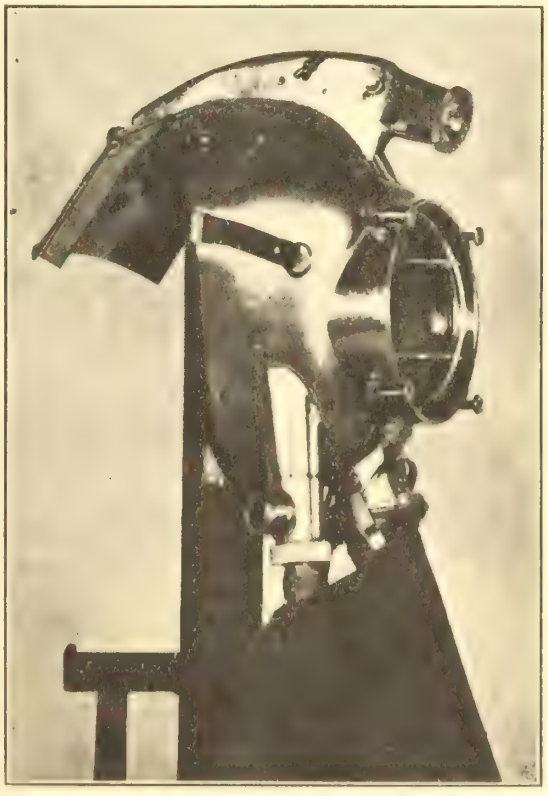
As publications relating to the Courrieres explosion have appeared in other countries, and as many lessons are to be learned from the circumstances of the explosion, a descriptive account of this shall be printed in the Mines Annals. This work will be undertaken by Engineer Heurteau.

The final investigations into the fire in the Cecile Seam have established the fact that it was a fire of but small proportions that attacked the mine timber and destroyed about 2,000 kg. of timber. This fire was not for any length of time so important and disturbing as the signs it gave off in the commencement of the rescue work, seemed to indicate.

These evidences strongly influenced all the measures taken as they appeared to threaten an immediate danger, which, as a matter of fact, was not so important as it looked.

The overrated importance of these evidences of fire lamentably hindered the work of rescue.

The exploration work in No. 3 pit, for the temporary cessation of which the engineers who had charge of the work of rescue, have been blamed, occupied afterwards no less than 37 days, and this with much better materials and under more favorable circumstances than presented themselves at first.



The restoration of the ventilation and the starting of the No. 4 pit fan, which were at that time so severely critized, are alone to be thanked for the steady improvement of the air to the south of shaft No. 3, as after events proved conclusively. It was through this that the thirty survivors were enabled to leave their place of refuge and reach the bottom of No. 2 shaft without being overcome by the after damp.

From the findings of the Special Commission held by Chief Engineer Carnot, it came out in the enquiry, that the stoppage of the exploration work in No. 3 pit and the restoration of the ventilation were justified by the results. In particular, it was due to the restoration of the air current that the thirty survivors escaped from what would otherwise have been certain death.

F. W. G.

THE DRAEGAR HELMET.

The above is a photograph of a Draeger helmet fitted with an electric lamp. The arrangement will leave free the hands of the man wearing the helmet for other work. The battery forms a flap at the back of the head, and the whole arrangement appears very compact. We do not yet know what the weight of the lamp and battery is. This is an important consideration, for any marked weight on the head would soon

become irksome. The Draeger people are also making helmets fitted with a device that will enable the wearer to speak to another man wearing a helmet or to persons outside the zone of unbreathable gases in which the wearer is working. In the latter case the rescuer will lay a thin telephone wire behind him as he advances, similar to the field telephones that were used by the Japanese in the late war. These additions are small but they all tell in the general efficiency of rescue work.

A RECENT DISCOVERY OF GOLD NEAR LAKE MEGANTIC, QUEBEC.

(Printed by permission of the Acting Director of the Geological Survey.)

Abstract of report by John A. Dresser.

A discovery of gold, which has recently attracted much attention in this district, has been made in the township of Marsboro, in the south-eastern part of the county of Compton, a few miles from the village of Lake Megantic. Lake Megantic station, on the Canadian Pacific Railway, between Montreal and St. John, is 175 miles from the former, and 307 from the latter place. It is also connected with Quebec city by the Intercolonial Railway, the distance being 115 miles. The place where the gold has been found is in the fifth range of Marsboro, principally upon lot nineteen. The distance from Lake Megantic station by road is about nine miles, but this can be shortened to less than six at seasons of the year when the lake can be crossed by boats, or sleighs.

The District.

Victoria bay, on the west side of Lake Megantic, and three miles from its northern end, is the most prominent irregular feature in its shore-line. The head of this bay is within a mile and a half of the gold locations. Victoria river, which empties into Victoria bay, is a stream some fifteen miles in length, and has several tributaries, the largest of which takes its head near Big Megantic mountain. Along the Victoria river a considerable number of prospecting licences have been lately taken out, the licence holders evidently considering that the discovery of gold in the rock of the neighboring hills is a favorable indication of the occurrence of placer deposits in the valleys.

Geology.

The areal geology of this district has been discussed by Dr. R. W. Ells, of the Geological Survey, in the annual report for 1886. The map accompanying that report shows the district to the northwest of Victoria bay—including the locality of the recently discovered gold and the valley of the Victoria river—to be occupied by sedimentary schists, and slates of Cambro-Silurian. They are dark or iron grey, fine grained sediments, with a good slaty cleavage. As their color would indicate, they contain small amounts of iron ore, and are somewhat micaceous. They give a rather even surface to the country, which in this vicinity is broken only by the prominent intrusion of Big Megantic mountain. So far as known, this is wholly a mass of granite. It rises abruptly above the surrounding country for 1,500 or 2,000 feet, and occupies between twenty or thirty square miles.

The area between the south end of Lake Megantic and the International Boundary Line, except for some granite hills, is occupied by rocks of a much earlier age; being a part of the Pre-Cambrian formation brought up from the folding of the White mountains. Large portions of it are known to consist of diabase and other basic eruptives. The intervening section is mapped as Cambrian. It is largely drift covered in the district in question.

The boundaries of the formations, and the strike of the rocks, are northeast and southwest: that is, parallel with the axes of the mountains on the southeast.

The surface of the entire district is generally covered by drift, which carries a large number of boulders—chiefly granite. Exposures of bed rock are few, and of small extent. Yet, the soil is not usually deep, and seems very evenly distributed.

Occurrence of the Gold.

At the time of the writer's visit, in April, 1908, no work had been done for several months, and the pits and trenches were filled with ice and water. Hence, samples showing a proper average of the fresh rock could not be obtained. The ground, however, was practically free from snow, and there was favorable opportunity for tracing out the relations and partial extent of the gold-bearing rock.

The rock which carries the gold in Marsboro is a fine grained granite, slightly porphyritic in structure, and it occurs in the form of dikes in the Cambro-Silurian slates. Three separate dikes were located. They were between fifteen and thirty feet wide—as far as could be ascertained—and all seem to be about vertical in position. One of them was traced by occasional exposures, for 600 yards. They have been much shattered and broken, and in places are quite schistose. In the cracks thus formed there are many small reticulating veins of quartz in some of which visible gold occurs. These veins are usually less than an eighth of an inch wide; although one, two inches in width was seen. The granite of the dikes consists of quartz, and feldspar, with a little muscovite, and in places contains grains of dolomite. Grains of chalcopyrite are frequently found in some parts of the dikes, and a little pyrite and galena are also to be ssen. The sulphides are, however, not limited in their occurrence to the little veins, as seems to be the case with the visible gold. The rock is often thickly spotted by iron rust; indicating that iron bearing sulphides were originally disseminated throughout much of the dike. No gold has yet been found in the slates on either side of the dikes.

In direction, the three dikes are practically parellel. Dike No. 1, on lot nineteen strikes N. 60 degrees W.; dike No. 2, which occurs on lot twenty and twenty-one, N. 55 degrees W; and dike No. 3, on lot twenty-one, strikes N. 60 degrees W. The direction of the cleavage of the slates in the few places where it could be seen, was found to coincide nearly, if not quite, with the dikes.

On dike No. 1, there are four exposures:

(A). A cutting about three feet deep has been made, exposing this rock at the edge of the woods which cover the western half of lot nineteen. Gold is reported to occur here.

(B). Two hundred feet northeast from A, a shaft has been sunk to a depth of twelve or fourteen feet. Visible gold can be occasionally seen in the rock of the wall, and of the dump. The shaft was largely filled with ice and water at the time of my visit. This is the place where the original discovery was made and Mr Obalski's specimen was taken from this pit.

(C). A hundred feet northeast from B, is a cutting three feet deep, from which visible gold is reported

A specimen taken from this place, showing no visible gold, and carrying a few grains of chalcopyrite, was assayed for mee by Mr. H. F. Strangways, M. Sc., at McGill University. The results obtained were:

Gold,	0.35 ounces at $20.00 equals ..	$7.00
Silver,	0.70 ounces at $0.60 equals ..	0.42
	..	$7.42

A. B. and C. are on lot nineteen and the width of the dike, as shown at these places, is between fifteen and twenty feet.

(D). Five hundred yards northeast from C, on the farm of Donald Smith, lot twenty, range four, the rock has been uncovered. This discovery disclosed the regularity in direction of this dike. There is no exposure of the rock between C and D; but it was found at the latter point by Mr. Smith, by carrying a line in the direction indicated by pits B and C, until his property was reached. Then, sinking through some eight feet of drift, he found the dike rock which is reported to carry gold.

A, B, and C are on the lands under lease to J. A. McIver and associates. The mining rights at pit D, are owned by Donald Smith.

On dike No. 2, no work has been done, and there are only two natural exposures some forty yards apart. The dike appears on lot twenty, a few feet from lot twenty-one, and running obliquely towards the boundary line. It probably enters that lot near the more northerly of the two exposures seen. Slate was found on both sides of it, but at some distance. This dike is not less than ten, nor probably more than thirty feet in width. It is 500 yards northwest from dike No. 1.

The mining rights on lot twenty are heid by Mr. McIver et al, and those on lot twenty-one, by Messrs. Gendreau.

On dike No. 3, which is forty yards northwest from No. 2, and thus is on lot twenty-one, a cutting apparently seven or eight feet deep has been made. The southeast wall is slate, that on the northwest has not been found. Mr. A. B. Gendreau, Lake Megantic, one of the owners, reports that the rock at this place yields a trace of gold.

Source of the Gold.

The gold has evidently been brought in by the granite of the dikes in which it is now found; since it iccurs in the rock as well as in the small veins. The subsequent shattering of the dikes by regional metamorphism, has afforded conditions for the concentration of the gold in the small veins in which visible amounts have been found.

Extent of the Gold-Bearing Rocks.

Thus far only three dikes have been found in this vicinity. But as little or no stripping has been done in search of them, since the natural exposures of bed rock are exceedingly few, and as the dikes yet found are near together, it seems likely that there are many others in the vicinity. Their number depends in a considerable measure upon the source of the dikes. Dikes are off-shoots from larger masses of related rocks which have filled cracks and crevices formed by the intrusion of the larger bodies. These dikes all trend directly towards Big Megantic mountain, some seven miles distant. This is an intrusive mass which has been thrust up through the surrounding slates, and, as far as known, is of granite, having a chemical, and mineralogical composition that could give rise to such dikes.

Alluvial Gold.

Following the announcement of the discovery of gold in the rock at Marsboro, a considerable number of licences have been taken up along the Victoria river. These appear to be held chiefly by placer miners from Beauce. It was late in the season when most of the licences were obtained and no work of importance has yet been done. With the lowering of the water in the early summer, the valley of the Victoria will probably b well prospected. At the time of writing no evidence of the value of these prospects is available.

Prospecting of the District.

It must be borne in mindthat the gold bearing rock at Marsboro is as yet known only in small amount, and that the proven occurrences of gold are few. While samples have been taken which appear to represent the general rock of the dikes, and hav been found to carry gold, they are after all only random specimens. Samples representative of each dike must be taken at many points before the commercial value can b distinctly asserted. At present there is no place exposed suitably, for the taking of such samples. The dikes are definite bodies, and can be easily uncovered by stripping, and fresh rock could be obtained at a few feet from the surface. Continuous specimens taken across the dikes at suitable intervals would soon make it easily apparent what the possibilities are for profitable mining.

The country is easy of access, and prospecting is not unduly expensive. Once recognizing the direction of the dikes, it is a comparatively simple matter to follow them, as was shown by the discovery of pit D, on dike No. 1, by Donald Smith. If the gold proves to be persistent and at all uniformly distributed in the rock, the district would admit of mining under favorable conditions. Labor in not highly expensive, timber is plentiful, water supply can be had at no great distance, and transportation difficulties are not excessive.

But first, the actual average values of the dike over long distances must be ascertained, and the mode of occurrence of the gold—whether evenly disseminated or unevenly distributed through various parts of the rock—must be found out. And these facts must be determined for each individual dike. Then, if these already found yield values to warrant it, the search for others should be made as already indicated.

Licences.

Prospecting licences.giving an exclusive right to examine the property, with the privilege of securing mining licences or of buying mining rights in the Province of Quebec, may be obtained from the Hon. the Minister of Mines, Quebec. These licences are granted for three months, and are renewable at the discretion of the Minister. The licence fee in surveyed private lands as at Marsboro, is $2.00 per 100 acres, or fraction thereof; a similar fee being required with each renewal. On November 24, 1907, the following lots were held under prospecting licences in the township of Marsboro:

Range 1, lots 17, 18; range 2, lot 19; range 3, lots 18-22 inclusive; range 4, 18-22 inclusive and 28; range 5, lots 16-22 inclusive; range 6, lots 13-20 inclusive; range 7, lots 12-21 inclusive; range 8, lots 10-14 inclusive; range 9, lots 7-14 inclusive; range 10, lots 7-14 inclusive; range 11, lots 4-11 inclusive and lot 4; range 12 lots 6-10 inclusive.

MINERAL LOCATIONS ON MORESBY ISLAND—ONE OF THE QUEEN CHARLOTTE ISLANDS.

(Abstract of Bulletin No. 1, issued by the British Columbia Bureau of Mines.)

(*Continued from last issue.*)

To the north of the tunnel, and on the Cash Box mineral claim in the cliff, there is, over a length of 100 feet, an exposure of magnetite carrying a considerable percentage of sulphides, chiefly pyrrhotite with some chalcopyrite.

Harriet Harbor.

Harriet Harbor lies to the west of Ikeda Bay and to the east of Huston Inlet, and is separated from each by mountains which run out into the sea in narrow arms, not over a mile wide at the head of the harbor, but two or three miles long.

The townsite of Jedway, with a wharf, store, post office, and several cabins, has been located on the southwest end of Harriet Harbor, and here the office of the Deputy Mining Recorder of the district is situated. It was on the shores of this bay that the first of the more recent mineral discoveries of the district were staked, by Watson and Thompson, in 1905. These discoveries may be considered the origin of the present activity in Moresby Island.

Copper Queen.—Probably the best known claim on this harbor is the Copper Queen, now held under bond by J. S. McMillan, of Seattle. The claim is situated on the southwest side of Harriet Harbor, some 5,000 feet from the water and 880 feet above it. On this claim, as on most of the claims in the district, the mineralisation consists of magnetite carrying variable amounts of copper pyrites, and upon the percentage of this latter mineral found depends the value of the deposits. When visited, the only development work done consisted of a large open pit in a small draw, made to expose and develop an exposure of magnetite found in a bluff on one side of the "draw." The work had succeeded in exposing a very considerable body of magnetite in a country rock, which appeared to be a much altered diabase. In the side of the cut there was exposed, dipping at an angle of 48 degrees, a body of magnetite 6 feet thick, of which the lower 4 feet 6 inches was almost solid magnetite, containing irregularly distributed bunches and stringers of copper pyrites. The upper 1 foot 6 inches of the ore body, although chiefly magnetite, was more mixed with rock matter and appeared to the eye to carry a lower percentage of copper. This face stood exposed for a height along its slope of 25 feet, with indications that it continued down under the dump and into the hill for some farther distance; at its highest point the ore body came out practically to the surface. An average sample of the exposed face of the ore body was carefully chipped off across the whole six feet exposed and at different places in its length; this sample assayed, copper, 1.4 per cent., with traces of gold and silver. Some 50 to 75 tons of mineral was piled up on the dump, and this also was roughly sampled, giving about 1.5 per cent. copper.

Some little distance up the creek from the open cut, and also about 300 feet to the east, are bodies of limestone, although none show in contact with the ore body.

Iron Mountain.—The Iron Mountain is another claim in the immediate vicinity, held by J. S. McMillan. On this but little actual development has been done, but stripping has exposed a similar body of magnetite of considerable size, showing copper pyrites along its margin.

Moresby Island.—The Moresby Island mineral claim lies somewhat to the south of the Copper Queen and is also held by J. S. McMillan. This claim overlaps to a considerable extent the Tate mineral claim, owned by T. J. Watson, as to the merits of which dispute no opinion is expressed. The first open cut seen showed a country rock consisting of a decomposed diabase or diorite, with a considerable quantity of secondary red garnets, in crystalline form, all showing copper stain and a small percentage of copper.

In the second open cut, near where a fine grained igneous dyke, of later origin, cuts through the country rock, there is a strong impregnation of iron pyrites and nearby a small seam of copper pyrites, while a certain amount of copper carbonate occurs in the rock matter, but no considerable body of ore has been exposed. A sample was taken of the exposed face of the cut, which gave, upon assay, copper, 2.7 per cent., wet assay, with traces of gold and silver. The face of the cut is about 10 feet long and 10 feet high, and was in at the bottom only 6 to 8 feet.

Reco.—The Reco mineral claim, held by J. S. McMillan, is located nearer the bottom of the hill, only 200 feet above and a quarter of a mile from the water. The country rock here is a much altered diabase, in which a deposit of magnetic iron, about three feet thick, is seen dipping into the hill at an angle of about 40 degrees, accompanied by a black hornblendic dyke and overlaid by a close grained silicious rock. The magnetite carries sulphides of iron and copper, the copper contents in the exposed face of the magnetite being estimated at from ¾ to 1 per cent copper. The exposure was visible for some 50 feet up the bed of the creek and was fairly uniform in character.

An inclined shaft had been sunk on the deposit and 3 sets of timbering, 5 feet apart, set up, below which the shaft is reported to have been sunk about 6 feet, but as it was full of water it could not be examined. A 16 h. p. boiler and a steam drill were on the ground, covered by a rough board shed. This boiler had formerly been used in prospecting the claims farther up the hill.

Huston Inlet.

Huston Inlet lies immediately to the west of Harriet Harbor and is a fine bady of navigable water. Some little prospecting has been done on its eastern shore, on the range of hills which separates it from Harriet Harbor, but the locality must as yet be considered as unexplored. The few recorded claims are quite unprospected and undeveloped, only a little surface scratching having been attempted.

Burnaby and Copper Islands.

Red Haven.—The Red Haven mineral claim on the south side of Copper Island, a claim recently re-staked by Abe Johnson and so named by him, is of interest as having been on the spot upon which Francis Poole and his party did their work in 1862-3, and where, about

five years ago, a prospector named Abe Heino, having re-located the property, did considerable work, the remains of which are still visible and excite in visitors much curiosity as to "what he was driving at."

Geologically, the island is similar to that portion of Moresby Island immediately to the south, and some two or three miles distant. The sedimentary rocks are so cut up by later volcanic rocks as to give the appearance of the limestones being the intrusions and the volcanics the country rocks.

In a little cove running into the island some 30 to 40 feet, with nearly perpendicular walls and a rocky floor, submerged at high tide, a tunnel was driven from the level of the rock floor for a distance of 35 feet, and from this tunnel a cross-cut had been started off to the right, towards the water, for some 10 feet. The work had been done along a limestone diabase contact, along which was visible a little magnetite carrying some copper pyrites, but in no place was the mineralization sufficient to be of any importance. The present owner has done no work on the property. The property is interesting, as showing what Poole spent two years upon, while so many much more promising showings were "sticking out of the ground" within three of four miles, on the larger island.

Sea King.—The Sea King mineral claim is a recent staking on the southwest side of Burnaby Island, by Captain Locke, of steamship "Princess Beatrice." On the beach, between high and low water, there is exposed a contact of limestone and fine grained trap, along which stands, exposed by action of the waters, a contact deposit of magnetite, from two to three feet wide, dipping at an angle of 80 degrees to the west. The magnetite carries some iron pyrites and a small percentage of copper pyrites.

In a small gulch, a short distance to the west, there is a light gray colored igneous dyke, fairly crystalline, and showing some horneblende, having a width of four or five feet, containing some stringers of calcite and also some magnetite and copper pyrites. Some little surface stripping had recently been done, with an idea of tracing out the contact, which was found to contain some copper pyrites.

Klunkwoi Bay.

On Saturday, August 31st, thanks to the courtesy of Mr. Ikeda, of the Ikeda Bay mines, the writer was loaned a gasoline motor boat with two men, and a start was made for a group of claims situated on Klunkwoi Bay, at the north end of Darwin sound, and inside of Lyell Island. The passages inside of Burnaby and Lyell Islands were taken, as being more protected from wind and sea. This inside passage is at all seasons suitable for a small boat, although the channel inside Burnaby Island is only a fathom deep at low water and is most tortuous and difficult to follow. The distance from Ikeda Bay to Klunkwoi Bay is about 45 miles, and the run was made in less than eight hours.

Swede Group.—None of the claims in this section of the island has been long staked, the first being the Swede group, staked in January, 1907, by Larsen, Pearson and Rogers. The group consists of eight claims, the Excelsior, Pearson, Larsen, Keystone, Bob, Anaconda, Seattle and Homestake mineral claims. The claims are so located as to cover a small peninsula projecting into Klunkwoi Bay and separating two smaller bays or fiords. This peninsula is not over 2,500 feet across and rises to a height above the water of about 1,000 feet, the average slope of the hillside being about 46 degrees, and this steep slope continues under the sea level, giving deep water at which any vessel can lie almost along the shore line. Although the claims had only been located for about six months, it was found that the owners had done a very considerable amount of development work which, as far as it had progressed, proved more than encouraging. The work consisted of a number of open cuts running horizontally along the hillside at intervals from the sea level to a height of 700 feet above. These cuts are on the Larsen claim, and may be said to have prospected a strip of hillside about 250 feet wide extending from the shore up to an elevation of 700 feet. The line of these cuts continued over the hill on to the south slope, has been further prospected on the Anaconda claim, and found there to be similar in all respects; therefore, it is to be presumed that the mineralized zone is continuous over the peninsula along the line prospected in a N. 63 degrees E. direction.

A short distance to the west of the workings a fault plane has cut across the peninsula, the line of its break showing clearly on the mountain side. To the west of this break the prospectors claim not to have found mineral, but it is suspected their investigation has not been thorough, as the geological conditions are the same on either side of the break, and it has not been a channel of infiltration of mineral. The country rock right across the peninsula appears to be uniform and the same, a much altered diabase,[1] cut by a few later trap dykes, which, however, do not appear to have any effect upon the mineralization.

As far as disclosed in the cuts, the 4 or 6 feet of rock lying next the surface contain very little mineral, but when this depth is reached the rock is found to become impregnated with copper pyrites and occasionally bornite, and this impregnation in the deeper cuts appears to be growing greater with the depth as far as the work had proceeded; this is, at the greatest, a depth of some 15 feet. Sometimes the chalcopyrite occurs in little granules, peppered all through the rock, and again it occurs in little veinlets, constituting an ore difficult to estimate the copper contents of by the eye.

Samples were taken from the most extensive of the open cuts, viz., the one at an elevation of about 75 feet above the sea level; of these a general sample gadded off the face over a distance of 75 feet horizontally, and for the height of the cut, except the upper "barren" six feet, gave upon assay better than 2 per cent. copper, with traces of gold and silver.

Another sample, taken by the writer, and which was intended to represent ore as it would be roughly handpicked, gave copper 5.7 per cent., silver 0.2 ounces to ton and trace of gold.

A third sample, taken from the south slope of the peninsula from an open cut on the Anaconda claim, gave 2.9 per cent. copper, with traces of silver and gold.

The occurrence of the mineral is such as to render hopeless any form of water concentration, and the ore would have to be smelted direct, but for such treatment it is admirably suited, as the gangue matter is self-fluxing and very easily melted.

To summarize the situation, the claims have not as yet been developed sufficiently to absolutely prove their ultimate value. They are still only prospects, but the success attending the development done commands attention and gives promise of an exceedingly large, but low grade, deposit of copper ore. The location of the

properties is ideal for the cheapest kind of mining, and the facilities for cheap transportation by vessel could scarcely be improved upon.

The grade of the ore, as already noted, is low, probably not higher than 2 or 3 per cent. copper, with little or no gold and silver values, but the fact is that the values have increased with depth, so far as development has proceeded.

Last Chance Group.—The Last Chance group of six claims, the Last Chance, Goodenough, Jumbo, All Right, No Doubt and Star, owned by Messrs. Wintermute, McEachern and Jones, lies to the southwest of and adjoining the Swede group near the shore of the next bay to the south. These claims are more recently located than the Swede group and have not had the same amount of development work done, but such as has been done, a couple of large open cuts, discloses conditions almost identical with those found in the Swede group, and, as the ore found is also in direct line with the mineralized zone on the Swede group, it is fair to suppose it to be a direct continuation of the Swede group deposit. The most important development work has been done on the Last Chance claim, at a distance of 1,600 feet from the bay, at an elevation of about 200 feet, and consists of an open cut in rock 45 feet long in a N. and S. direction, across the ore body, and has a face of six feet in depth. A general sample, made up of small pieces broken off the ore already mined, gave, upon assay, copper 2.7 per cent., silver 0.4 ounces to ton, and trace of gold.

The country rock has been classed, after microscopic examination, as a "Porphyritic diabase."[2]

As far as the development has gone, these claims give promise similar to the Swede group, and the camp as a whole indicates the presence of very large quantities of low-grade copper ore. The deposits are so admirably situated for cheap mining and transportation, the character of gangue matter is such as to permit of very cheap smelting, so it is estimated that such ore is well within the commercial limit and can be treated at a profit, despite the fact that there is no appreciable quantity of gold or silver present.

The formation in which these deposits occur would appear to extend for a considerable width east and west, and is found again to the northwest on the shores of Skidegate Channel, near the Narrows, constituting a large area of territory which may prove productive.

On Septemeber 2nd, the trip northward was resumed in the gasoline launch to Skidegate, a further distance of 45 miles, a stop being made at the Old Shaft, some seven miles south of the Sand Spit.

Old Shaft.—The Old Shaft, judging by the size of trees growing on the old dump, was sunk some 40 or 50 years ago, but by whom it is not known, nor does there seem to be any Indian tradition regarding it. The property has recently been taken up again by Shelden and Shabbard, who have bonded it to D. R. Young and associates, who were unwatering it, employing one white man and two Indians. At that date the shaft had been unwatered to about 90 feet depth, and the foreman reported having sounded it for a further depth of 45 feet. Some short distance above the 90 foot mark, two cross-cuts had been found, one to the east and one to the west, extending about twenty-five feet from the shaft. The shaft had not been cleaned out, so, of course, nothing was visible in it as to ore.

The country rock in the vicinity, as exposed on the beach, is an agglomerate, in which a fissure was seen a few inches wide, carrying copper pyrites in quartz. Selected samples of clean mineral assayed 10 per cent. copper and two ounces of silver to the ton. This fissure led directly to the old shaft, distant only a few feet, and it was evidently on this fissure that the shaft had been sunk and along which the two cross-cuts had been driven. The fissure, as seen on the beach, was too small to be of any importance, and the old dump exhibited no commercial ore.

Gold Harbor.

Mr. John McLellan, a British Columbia assayer, has been working during the past summer at Gold Harbor, a bay of Moore Channel, on the west coast of Moresby Island, just south of Skidegate Channel. It was at this point the Hudson Bay Company, in 1852, found and mined a deposit of gold bearing quartz. Mr. McLellan examined the old workings but could find no continuation of the values, though he discovered in the vicinity another small quartz vein carrying gold in considerable proportions. He reports the vein as being rich but very small; he erected last season an arrastra driven by water power and managed to extract a certain amount of gold, bringing a small "brick" to Victoria.

---

[1]Microscopic examination made by Dr. Dresser, of McGill University (4,613).—This is a massive, dark green, fine grained rock, showing spots of epidote, and a few grains of pyrite and pyrrhotite. It is found to consist essentially of plagioclase, feldspar and pyroxene. There are also present accessory magnetite, as well as the secondary minerals, chlorite and leucoxene. No quartz or olivine could be found. The structure is ophitic, and the rock is consequently a diabase.

[2]As result of microscoic examination, Dr. Dresser, of McGill University, reports: "The rock is fine grained and of a uniform green color. The slide is found to be much decomposed. Feldspar is present in a few phenocrysts and in more numerous small lathe-shaped crystals of plagioclase. There are numerous grains of augite and epidote with much chlorite, the latter being in larger irregular masses. It is a Porphyritic diabase.

DIABASE AND GABBRO.

The diabases are principally composed of plagioclase, augite, magnetite, and sometimes olivine. They have a somewhat wide range in composition. Silica may be present from 49 per cent. to 57.5 per cent.; alumina from 12 to 18 per cent.; ferric and ferrous oxides together from 8 to 13.5 per cent.; magnesia up to 11 per cent.; lime up to 11 per cent.; the alkalies up to 6.5 per cent. There are, of course, many minor constituents.

The gabbros consist mainly of plagioclase and pyroxene, with various admixtures of other minerals. Silica ranges from 45 to 56 per cent.; alumina from 13.5 to 30.5 per cent.; ferric oxide up to 3 per cent.; ferrous oxide up to 15 per cent.; magnesia up to 16 per cent.; lime up to 17 per cent. Alkalies and other minor constituents are present in small amounts.

SAMPLING OF MINE DUMPS.*

By Henry S. Munroe.

It frequetnly happens that mine dumps contain low grade ore, originally rejected as too poor for treatment which later, under more favorable conditions, may be worked with profit. The old waste dumps may thus constitute an important asset of the mine, the value of which must be accurately determined. The sampling of such waste dumps presents a difficult problem. Portions of the dumps which have accumulated during periods of active development; for example, during the sinking of a shaft or the driving of a tunnel, may be absolutely barren; while other portions representing the growth during periods of wasteful or careless management, may be very rich. In any case the distribution of values is likely to be very irregular. If the dumps be formed in the ordinary way, by dumping cars at the top of the bank, the stratification, and therefore the zones of rich and poor material, will be in inclined layers. Moreover, as the cars are dumped at the top, the larger pieces tend to roll to the bottom of the slope, while the fine stuff lodges and remains near the top. The upper portion of the dump, as containing most of the fine material, is therefore likely to be rich; and the bottom, consisting of lumps and coarse material, is in general poorer than the average.

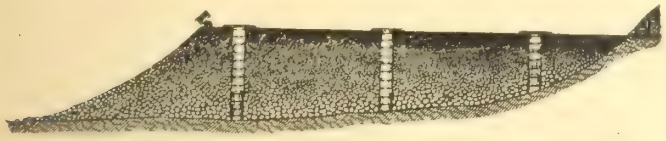


FIG. 1. Longitudinal section of a mine dump with shafts sunk for sampling.

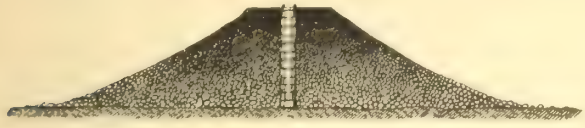

FIG. 2. Cross section of a mine dump with sampling shaft.

Figures 1 and 2 are intended to illustrate this sizing effect, which has been purposely exaggerated in the drawings. In practice many large lumps will remain in the upper part of the dump and some fine stuff will be caried down the slope. The outside of the dump represents in most cases the later additions only, and the material deposited in earlier years is deeply buried. Finally, the dumps will contain much ore and rock in very large lumps and a due regard to the effect of such large pieces on the value of the sample taken, will necessitate handling large quantities of material. For example, if we adopt the inch-ton sampling scale,* the presence of ten inch pieces would indicate one hundred tons as the minimum total weight of samples to be taken. Or even if we take a two-and-a-half-inch-one-ton sampling scale, the presence of many lumps 25 inches in diameter will lead to the same result.

The usual method of sampling a dump is to take numerous small samples from the sides and top, which are either assayed separately or united to make one or more large samples. If this method be followed the points to be sampled should be determined by measurement, either at the corner of 25-foot squares, or better, in some cases, located on contour lines at uniform distances apart. In either case the samples should be given weight in the final average in proportion to the amount of ore that they may represent in the original pile, bearing in mind the probable concentration in values at and near the top of the dump. If the samples be located on contour lines, those on each contour may is essential. If the crushing be done by hand, with be combined and averaged separately, and the value

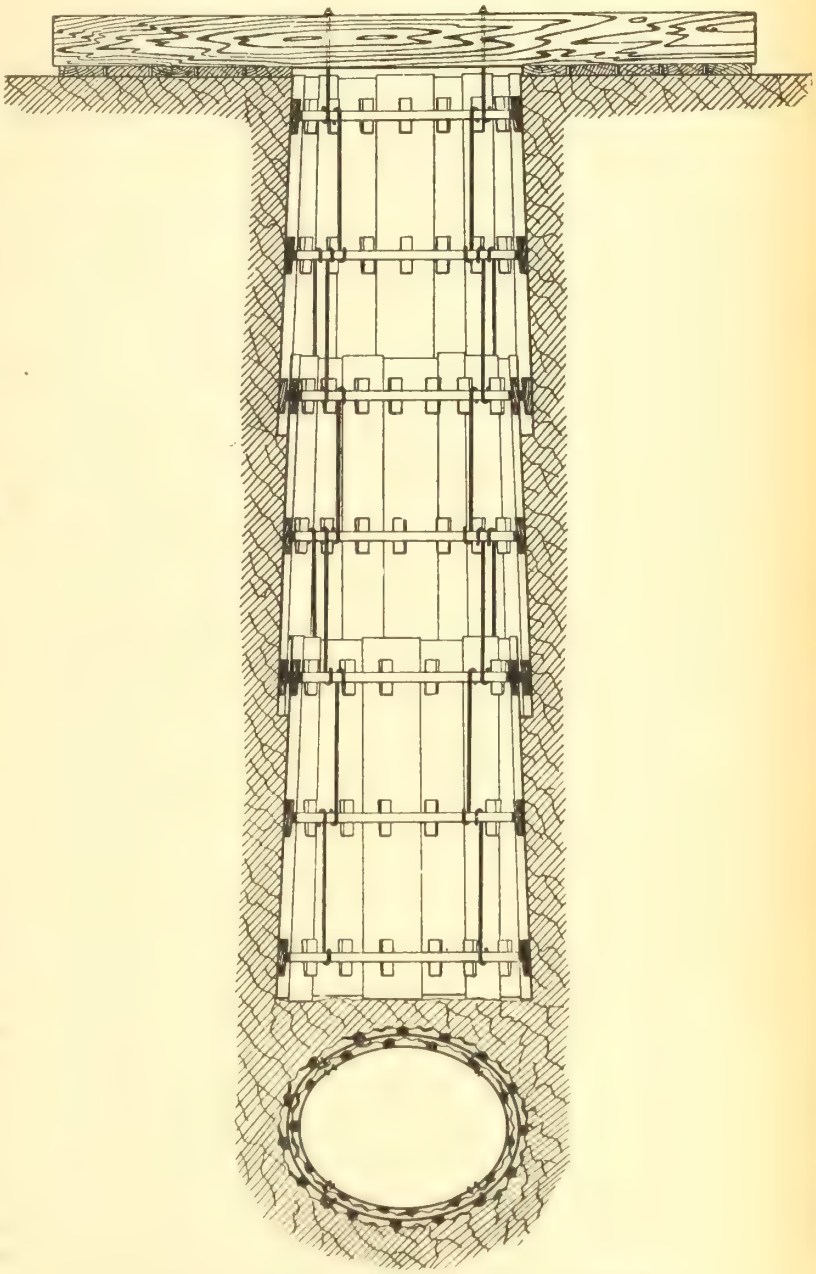

FIG. 3. Shaft lined with corrugated iron. Scale $\frac{1}{24}$.

for each contour averaged on the basis of the horizontal dump area represented.

In dump sampling, on account of the large amount of material to be worked down, a small crushing plant hammers and by mortar and pestle, a large force of men is necessary and the effective protection of the

*School of Mines Quarterly, Columbia University.

samples is made difficult. The crushing machines should be somewhat larger than the usual laboratory size and should have a capacity of several tons per day. The crushing plant may be installed at some central point where power is available and where the necessary counter shafting can be erected. Such a plant will be expensive, but in an important examination may save its cost several times over.

Last year the writer had to determine accurately the value of some very large dumps at a mine in Bolivia. In order to avoid the sources of error incident to sampling in the ordinary way, and to reach the deeply buried portion of the dumps, which were believed to be rich, it was decided to attempt the sinking of vertical shafts through the dump to obtain the desired samples. The advantages of this method of dump sampling are evident. Each shaft traverses numerous inclined layers of which the dump is composed and thus represents the accumulations of several years and not recent additions only. By dividing the excavated material into a number of samples, each representing five or ten feet of depth, the distribution of values from the top to the bottom of the dump may be studied, and each sample given its due weight in the final average, in proportion to the volume of ore represented. Finally, if the shafts be pushed to the bottom, not only are the deeply buried portions of the dumps reached and their value determined; but points in the original surface of the ground, on which the dump has been built, are located; from which points the contours of such buried surface may be determined, and the actual cross sections and volume of the dump computed with a greater degree of accuracy.

In order to limit the amount of material from each shaft and avoid the expense and delay of crushing unnecessarily large samples it was decided to sink shafts of as small diameter as practicable. In the loose and dry material of the dumps not only was a shaft lining required, but in all cases it proved necessary to drive the lining down every few inches, as the sinking progressed, or in other words some form of spiling or poling was essential to success. Suitable plank and timber for such work are not easily obtained in Bolivia and are expensive. Plank and timber also take up much room in the shaft, requiring that the excavation be made larger than desirable. Under these conditions it was decided to try the experiment of using light iron rings instead of timber, backed by sheets of corrugated iron instead of a wooden lining. Corrugated iron is largely used in South America for building purposes and is therefore kept in stock and was readily obtainable in sufficient quantity and at reasonable cost. This material, cut into pieces of suitable size, made excellent poling boards, light and stiff and occupying but little space in the shaft. By reason of its smooth surface, the iron sheets drive easily with but little friction, requiring light blows only of a three-pound hammer. After experimenting with sheets of different sizes it was found that the best results were obtained with pieces about five feet long and a foot or less in width. To support this corrugated iron lining, elliptical rings of ⅜ by 1 ½inch bar iron were used, the ends being welded together. The rings were made of elliptical rather than circular form to permit the large bottom rings of each set to be passed through the smaller upper rings. Also the elliptical form, for equal areas, gave the workmen more room for pick work and shoveling. These rings were supported by hooks of ⅜ inch rod as shown in the sketch, Figure 3. After experiment with rings of different sizes, the dimensions indicated in the figure were adopted, the middle ring being 32 by 28 inches and the upper and lower rngs respectively two inches smaller and larger each way. A shaft of these dimensions can be sunk rapidly and gives a sample of manageable size. With small men it proved practicable to use rings of less dimension than this. In one case a shaft was sunk successfully to a depth of 22 feet with rings averaging 22 by 28 inches. In all, 9 shafts were sunk in 8 weeks' time, the deepest being about 60 feet. This system of shaft lining, though composed of light material, possesses considerabls strength and stiffness. The overlapping of the corrugated sheets and the double rings, tightly welded together where the sections join, add much to the strength of the lining. The hooks are elements of weakness as these will straighten out at about one-fifth of the ultimate breaking strength of the rods. The strength of these hooks may be increased by always inserting the point of the upper hook in the space between the ring and the corrugated iron sheets, and by fastening the point of the lower hook to the rod with a slip ring. The work of shaft sinking will be facilitated by having on hand extra hooks, shorter and longer than the standard length.

AN ELECTRO-MAGNET FOR TESTING THE SUITABILITY OF AN ORE FOR MAGNETIC SEPARATION.

By L. H. L. Huddart, Associate.

Paper read before the Institution of Mining and Metallurgy, April, 1908

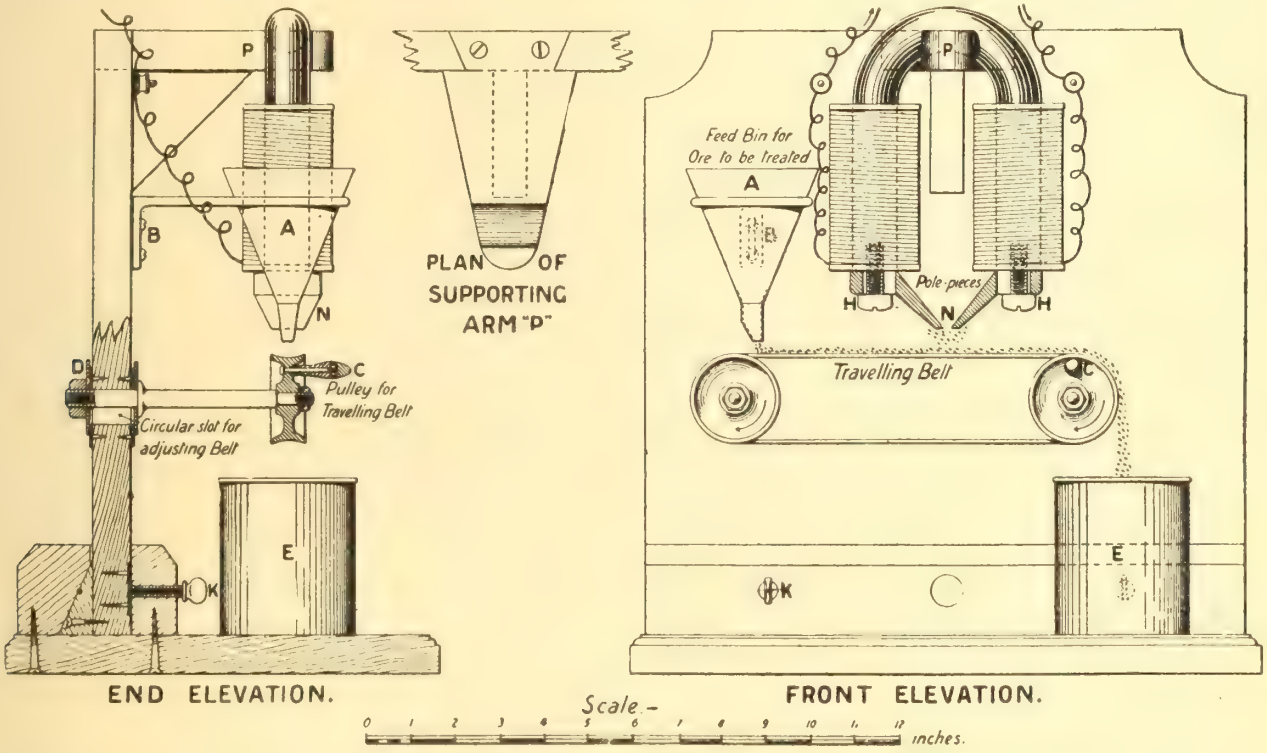
In the course of the discussion upon the paper by Mr. Amos Treloar and Mr. Gurth Johnson, it was suggested that any sketches describing a suitable small electro-magnet would be welcome to those interested in the separation of minerals magnetically.

The following note is therefore contributed in the hope that it may be of some little use.

The sketch shown illustrates an apparatus that has been found to be convenient for the quantitative determination of the separation to be expected in treating a given ore by means of a powerful magnet. In general, better work will be done by a laboratory apparatus than by a full-size machine. At the same time, the performances of the former will have a fairly constant difference from that of the latter, so that a good idea of the way to proceed with a given ore will be obtained.

Sampling.—A small machine will deal with only a small quantity, and to obtain representative results of value it is essential that the sample used should be a fair one of the whole ore. As much care should be taken in obtaining the sample as is ordinarily employed in preparing ore for assay.

Reduction.—The size of particles will depend upon the nature of the ore and the method of occurrence of the minerals which it is desirable to separate. They should not be too fine to commence with. Careful ex-



amination of the material that passes the magnet and falls into the hopper, E, will show to what extent further reduction is necessary. It is often useful to look at the discharged particles under the lower power of a microscope.

Further experiments should be made to find out to what extent the separation should be divided into stages.

Magnetic Field.—The most suitable strength for the magnetic field into which the sample will pass as it is carried along by the belt can be found by experiment. Commence with a low field, and extract the more permeable minerals first.

Such minerals as magnetite and magnetic pyrites should be taken out first with an ordinary horseshoe magnet.

The Apparatus.—The machine, as shown in the illustration, consists essentially of a 6-inch soft iron electromagnet, with 1-inch core, fitted with brass bobbins

wound with 18 B.W.G. copper wire. Two special pole pieces (N) are provided; they are slotted to allow of the adjustment of the air gap.

The magnet is suspended from a bracket on a hardwood stand, the back of which is secured to the base by means of two pinching screws (K). The arrangement shown in the sketch was designed to give a rigid, yet easily dismounted, attachment.

Upon the same stand there is also mounted a copper hopper with a support slotted to allow of vertical adjustment. This hopper feeds on to an endless belt running on two grooved pulleys, one of which has a small handle, C. These pulleys have about ¾ inch adjustment in each direction, to permit of the belt being placed into the required position beneath the pole pieces.

Method of use.—After suitable reduction, the sample (or part of it) is put into the hopper, A. The rate of feed to the belt depends upon the height of the spout above it; in this manner the feed can be adjusted to some degree of nicety.

The endless belt is driven by hand by means of the small handle, C, and the ore travels slowly beneath the pole pieces.

The distance of the belt below the poles can be varied by slackening the nuts, D, which clamp to the back the small shafts upon which the pulleys run. A suitable distance is found by trial. The ore that is not picked up by the magnet is carried on and falls into the hopper, E.

After running a short time, if there is much magnetic material present, it will have to be removed from the pole pieces, which is conveniently done by placing a piece of stiff paper, or sheet copper, beneath the poles and switching on the current.

The strength of the field is varied by loosening the screws, H, and moving the pole pieces closer or further apart, according to whether a stronger or weaker field is required.

The current may be supplied by a hand dynamo, off the mains, after a suitable resistance has been inserted, or by means of a secondary battery. Two cells do admirably. The battery is the most convenient, and, in a case, is very portable; but of course it is only available when there is a source of current by which it can be charged from time to time.

The sketch shows a form designed for use in the field, with a hand dynamo of 3 amperes at 10 volts and 3,000 revolutions per minute. A pocket ammeter to 5 amperes is useful.

The whole takes down and packs into two boxes, which are about one man's load, and can easily be transported by carriers. The cases are carefully fitted, so that no movement is possible within them.

The form of instrument which has been described was made for the author's use in Africa.

Those who are interested in this subject will find useful information in the admirable paper by Mr. T. Cook, A.R.C.Ss.I., F.G.S., on the "Use of the Electromagnet in Petrography." (Science Progress, No. 5, July, 1907.)

Air pressure at start, 105 pounds.
Air pressure while running, 102½ pounds.
Size of first drill, 1½ inches.
Size of last drill, 1¼ inches.
Inches drilled per minute, 5.46.

Nipissing Mine, May 7th, 1908

Name of machine.—Murphy No. 3.
Weight.—60 pounds.
Hole.—45 degrees above horizontal.

TIME.

Drills.	From Start.		Drilling.		Changing Steel.	
	Min.	Sec.	Min.	Sec.	Min.	Sec..
	.	0	.	..	.	..
1st.	1	30	1	30	.	..
	2	10	.	..	.	40
2nd.	3	15	1	05	.	..
	3	40	.	..	.	25
3rd.	4	05	.	25	.	..
	4	55	.	..	.	..
4th.	5	30	.	35	.	..
Total	5	30	3	35	1	55

Second time for steel to be used.
Hole collared to start, 1 inch.
Net depth drilled, 37¾ inches.
Net depth driled, 37¾ inches.
Inches drilled per minute, 6.86.

Note.—The Sullivan machine is constructed so as to dispense with the collar on the shank of the steel. A striking block is inserted between the hammer and the steel. This is a slight sacrifice of efficiency for cleanliness.

CANADIAN MINING INSTITUTE.

Members elected at council meeting, May 2nd, 1908: H. S. Badger, M. E., Richardson Mines, N. S.; J. W. Bryant, M. E., Box 665, Victoria, B. C.; J. T. Fee, M. E., Cobalt, Ont.; Geo. L. Fraser, Mine Superintendent, Cobalt, Ont.; B. W. Lawson, Cobalt, Ont.; G. F. McNaughton, Cobalt, Ont.; A. H. Sancton, M. E., c/o Mussens Limited, Cobalt, Ont.; Bert. N. Sharp, M. E., Orient, Washington, U. S. A.; Robt. Turnbull, C. E., 23 Lake street, St. Catharines, Ont.; C. G. Williams, M.E., Cobalt, Ont.

Associates:—L. O. Armstrong, 221 Milton street, Montreal, Que.; Spencer Benerman, Midway, B. C.; C. L. Campbell, Box 85, Cobalt, Ont.; W. Teese Curran, Mine owner, 300 St. James street, Montreal, Que.; E. L. Douchette, Room 53, 112 St. James street, Montreal, Que.; G. A. MacPherson, M. E., Niagara Falls, Ont.; D. B. Rochester, Cobalt, Ont.; Robt. T. Walker, Cobalt, Ont.

Application has been received for membership from Mr. A. G. Larson, Superintendent of the Le Roi Mining Company, Rossland, B. C.

The following applications have been received for membership in this Institute during the past week:—A. G. Larson, Superintendent Le Roi Mining Company, Rossland, B. C.; R. P. Williams, Rossland, B. C.; Fred S. Peters, foreman Le Roi mine, Rossland, B. C.; W. S. Rugh, accountant Le Roi mine, Rossland, B. C.

INDUSTRIAL PAGE.

The Western Fuel Company of Nanaimo, B. C., have recently ordered from the Robb Engineering Company a 600 horse power 24 inch by 42 inch Robb-Armstrong Corliss engine for driving one of theim mine ventilating fans.

The Dominion Iron and Steel Company have recently ordered from the Robb Engineering Company one 20 inch and 28 inch by 36 inch tandem compound Corliss engine for endless haulage at their mines in Wabana, Newfoundland.

The Longest Narrow Gauge Light Railway in the World.—This descriptive pamphlet, a reprint from Engineering of July 19th, 1907, is issued by Messrs. Arthur Koppel, light railway engineers, 27 Clements' Lane, London, E.C. It gives an account of the Otavi Railway in German Southwest Africa, constructed for the Otavi Mines & Railway Company by Messrs. Arthur Koppel. It is the longest narrow gauge light railway in the world. It connects the Otavi copper district with Swakopmund, the only available shipping port, a distance of 361 miles. The construction was started in August, 1903, and was completed towards the end of 1906. During this period the rising of the Hereros complicated the labor question. Italian workmen were secured, but trouble again ensued. Finally Italian and Ovombo workmen completed the task. The whole story of construction is a modern romance.

Bulletin No. 1065, Side Dump Cars—The Atlas Car & Manufacturing Company, Cleveland, Ohio.—The varieties of the Atlas Car Company's side dump cars are illustrated in this bulletin. These are modifications of their Standard No. 217 car. Except two scale charging cars, equipped with scales for the weighed various classes of material used in smelters, concentrators, blast furnaces, etc. (Nos. 217-W and 217-OW.), these cars are all either-side-dumping. The steel bodies with malleable iron rockers and corners braced with steel forgings are strong and rigid. The frames are made heavy enough to guarantee a substantial factor of safety over the maximum load.

In No. 217-S, with capacity from 1 to 2 yards, the malleable iron rockers are recessed on both sides to engage the bale. The car can thus be hold in a semi-dumped position, which greatly facilitates loading. In this position the distance from top of rail to edge of loading side is but 22 inches. Special types are the Side Dump Electric Motor Car, Scale Charging Car, and One Side Rocker Dump Scale Car.

Sullivan Stone Channelers—Sullivan Machinery Company, Chicago, U.S.A.—Catalogue No. 61.—The channeler consists of a reciprocating engine, operated by steam or air power, mounted on a standard, and driving a steel bit, or gang of bits, fastened to the lower end of the piston rod. The standard is mounted on a frame or car, which runs on a track and is propelled back and forth by a feed engine. By cutting a narrow slot to any needed depth into the rock the channeler separates a portion of the whole mass without shattering. In quarrying the stone is channeled in four or even six sides and waste is entirely avoided.

Channelers are suited to quarrying marble, sandstone, limestone, slate, and soapstone. They are of three types—"rigid head" machines for vertical cutting, "swivel head" for marble and slate, and a third type for undercutting or horizontal channeling.

The catalogue describes the work and equipment of these machines.

The cutting capacity of the channelers is indicated by the fact that, under 100 pounds steam pressure, the Sullivan "VX" machine will cut sixty to seventy-five feet per day of Vermont or Pennsylvania slate. In soft Virginia soapstone the cut is from 150 to 250 feet per day. The total weight of the different types of channelers, including equipment, but without boiler, ranges from 23,300 pounds to 5,740 pounds.

EXCHANGES.

The Colliery Guardian, May 1st, 1908.—It is pointed out by the Colliery Guardian that ambulance work in the mine should precede rescue practice in the experimental gallery. "With regard. . . .to the saving of life in the coal mine, there is need for something more than the ability to wear a given pattern of breathing apparatus, and to perform a certain amount of laborious work under such conditions. The rescuing party must be trained to work together with a common object, rather than indivdually to vie with one another in penetrating long distances into the mine. . . . .By ambulance work in the mine, we do not mean the ordinary routine drill of a St. John Ambulance class. . . . What seems to be required is a special kind of ambulance instruction, adapted to the conditions present in the pit after an explosion or any other disaster of the first magnitude."

Mining and Scientific Press, May 9th, 1908.—In celebration of the arrival of the American fleet in the Bay of San Francisco, Mr. T. A. Rickard contributes an article entitled, "From Mine to Battleship" to this issue. His theme is white lead. He traces the story of its manufacture. From the lead mine, the reader is brought to the furnace, the pigment factory and, finally to the navy yard where the battleship is made whitely beautiful.

The Selby smelter, at the northeastern end of the Bay of San Francisco, supplies the white lead used at the Mare Island navy yard. One of the mines, from which ore is sent to the Selby works is the Bunker Hill and Sullivan, the most important single lead producing mine in America.

The Bunker Hill and Sullivan produces 40,000 tons of lead and 1,650,000 ounces of silver annually. The property is situated at Wardner, in the Coeur d'Alene, Idaho. The ore is found in old quartzite, which has been much metamorphosed. The galena has been deposited in the resulting cracks and fissures. Silver is associated with the ore in the rates of one ounce of silver to 44 pounds of lead.

A certain rough alignment of irregular ore bodies marks the continuity of the lode. The quartzite is full of slips and fractures, which serve as local boundaries for the richer bodies of galena. The galena replaces and impregnates the brecciated quartzite along channels created by the fractures extending along the footwall and away from it into the overlying rock. The ore is mined with little waste, and goes to the mill for crushing, classification and concentration. Argentiferous galena is the chief product, but there is also iron pyrites which carries silver. The problem is to save the lead and silver without the zinc.

The ore first falls over 1¼ inch spaced grizzlies, the oversize going to a Comet gyratory crusher, which crushes it to a maximum diameter of 2½ inches, and then spills into a horizontal bucking belt, where a couple of men are stationed to pick out the clean ore (galena) and the mine rubbish by hand. The belt delivers to roughing rolls, and from them, reduced to a size of about 40 millimetres, the ore is discharged onto an incline belt conveyor. Here it is joined by the undersize from the grizzly. The joint product is carried to the top of the mill proper and is fed into two Vezin samplers, one of which extracts as a sample one tenth of the total, and the next a tenth of the sample. One per cent. therefore is the final sample. This is reduced and prepared for assay daily.

The ore now drops into mill bins of 600 tons capacity, equivalent to a 12-hours supply. After passing through trommels a part of the ore (between 18 mm. and 36 mm. diameter) goes to the bull-jigs. The jig concentrate is shipped to the smelter and the middling is reground. The other oversize from the trommel is reground and again passed through the trommel, and thence to the jigs. Huntington mills, Spitzkastens, Callow settlers, Frue vanners and Wilfley tables complete the outfit. The principal features of the mill are the re-crushing by rolls, the passage of the coarse middlings through the rolls, and the grinding of the fine middlings in Huntington mills.

In March of this year, in 28 working days, the mill treated 30,600 tons of ore carrying 12.56 per cent. lead and 5.07 ounces of silver. The ratio of concentration was 4.6 into 1. Of the 7,686,720 pounds of lead and 155,142 ounces of silver contained in the ore, respectively 5,965,096 pounds of lead and 111,598 ounces of silver were recovered, or 79.4 per cent. of the lead and 71.9 per cent. of the silver, 77.6 per cent. total recovery. Fifty-two men are employed in the mill. The total cost of milling in March per ton of crude ore was 35.9 cents. Besides the concentrates saved in the mill, varying amounts of picked ore are shipped direct to the smelters. The total cost of freight and smelting is $19.61 per ton. The grand total for all operating costs is $2.438 per ton.

The Selby Smelting and Lead Company works were founded in 1868. Twenty-five thousand dollars worth of gold and 12 to 15 million ounces of silver are refined here annually. The chief supplies of argentiferous lead ore and of silicious gold-silver ores come from Idaho and Nevada respectively.

From the bins the ore and concentrates are taken to the feed floor where they are shovelled by hand into the blast furnace. This is 36 by 144 inches. The blast is under a pressure of 33 to 34 ounces per square inch. From 130 to 140 tons of charge is treated per day, exclusive of fuel or slag. Of the charge 60 to 70 per cent. is ore. It is the aim to have 15 per cent. of lead on the charge.

The charge of 7,700 pounds is made up of slime briquettes, roasted matte, limestone, ore, refinery by-products (mainly litharge), metallic iron, and coke. To this 20 per cent. of old slag is added.

The roasted matte contains 12 per cent. lead, 12 per cent. copper, 45 per cent. iron, 3 per cent. zinc, and 7 per cent. sulphur.

The scrap iron bought as flux often includes typewriters, frying pans, rifles, stoves, sewing machines and many other miscellaneous items.

When the copper accumulates in the matte beyond 16 per cent., it is re-smelted and brought up to 45 to 55 per cent. The matte and the pyritic ores are roasted in Ropp furnaces, provided with travelling mechanical rabbles.

From the blast furnace the lead flows into moulds and is cast into bars weighing 100 pounds apiece. These are elevated to the upper floor of the refinery. Here the process of liquation is carried on. The metals are separated by the difference in their smelting points. The softening furnace is the next step. The lead is now free from antimony, arsenic, and other impurities and is tapped into desilverizing kettles, made of cast iron and fired by oil. At 840 degrees, F., a slab of zinc, added to collect the silver and gold, melts. The zinc is skimmed off and when pressed carries 3,000 to 3,500 ounces dore. The lead, free from silver and gold, contains now about 0.5 per cent. zinc. This is eliminated in a reverberating furnace. The lead is cast into 100 pound pigs and is taken to the white lead plant.

The refined lead is now "corroded into white lead—a compound of lead carbonate and hydrated lead oxide. From 2,100 tons of refined pig lead the Selby plant manufactures 2,500 tons of white lead per annum. The lead is exposed to the corrosive effects of acetic acid, in specially built temporary stacks. The treatment requires 100 days of undistributed chemical action. The corroded lead is then separated from the uncorroded and ground and screened. After much special treatment it is finally turned out as commercial white lead, ready to be used on the armoured sides of Uncle Sam's noble fleet.

PERSONAL AND GENERAL.

Mr. Frank C. Loring has returned from London, England, where he spent the last two months.

Mr. Jules Labarthe of the Consolidated Mining and Smelting Company, Trail, B. C., has returned from Colorado.

Our thanks are due the Bureau of Mines, Ontario, for copies of the map of Larder lake, compiled by

Messrs. Brock and Bowen. The map is on a large scale and the geological legend is instructively simple.

Mr. A. J. McMillan, general manager of Le Roi mine, met Mr. T. D. G. Drayton, chairman of the Board of Directors, in Chicago.

Mr. B. A. C. Craig has returned from a visit to northern Manitoba. Mr. Craig has taken up some valuable clay properties in that district.

Mr. Francis J. Peck, of the firm Francis J. Peck and Company, Williamson Building, Cleveland, Ohio, has gone to report on a mining property in Southern Mexico for Cleveland capitalists.

Professor Manley B. Baker, of the School of Mining, Kingston, pased through Toronto on his way to Cobalt on May 19. From Cobalt, Mr. Baker will take a geological party to Lake Abitibi for the season.

Mr. Arthur Koppel, the founder of the Arthur Koppel Company of 66-68 Broad street, New York, died in Berlin, Germany, on May 13, of heart failure. Mr. Koppel was in his 57th year. He was born in Dresden, Germany, in 1851. At the early age of seventeen years he started in business. In 1876 he established the present firm, taking up the manufacture of all kinds of material for narrow gauge railroads. Through his energy and foresight the portable industrial track was given wide popularity. In 1905 the firm was made a stock company. It now owns fifty-two branch houses, distributed practically all over the world. The American business was established ten years ago. In 1906 Mr. Koppel purchased 700 acres of property in Beaver County, near Pittsburg, Pa., where he founded the township of Koppel and erected a thoroughly modern plant. Mr. Koppel's death will not affect the organization.

BOOK REVIEWS.

A Pocket Handbook of Minerals, by G. Montague Butler, E.M.—16 mo., IX + 298 pages, 89 figures. Morocco, $3.00. John Wiley & Sons, New York, 1908.— The first thing that strikes one about this neat volume is its convenient size. It is easily portable. In one of the capacious pockets of the regulation khaki prospectors' jackets it would be scarcely noticeable.

Another prominent feature is the blank space left throughout the book for field notes and remarks.

Again, the most important characteristics of each mineral are emphasized by means of heavy face type. This serves to impress upon the reader the distinguishing traits of a mineral.

The systematic arrangement by paragraphs is convenient and time-saving. The plan followed is as follows:

Dana Number. Name. Composition. Hardness.
Lustre.
Color.
Streak.
Cleavage or parting.
Tenacity and fracture.
Degree of translucency.
Specific gravity.
Miscellaneous (magnetism, taste, odor, dichroism, etc).
B. B. (before blowpipe). Here are included simple chemical tests.
Methods or habits of occurrence and crystal habit.
Description of varieties.
A list of resemblances for comparison.
A short statement of uses.

The title page informs us that there is little reference to chemical tests. Since the book is intended to be used chiefly as a guide in field work, this omission is wise. Usually the prospector must rely upon the simple physical tests of hardness, color, streak, lustre, fracture and specific gravity to guide him. The blowpipe is not often called into requisition by the prospectors.

There are supplementary chapters upon commercially important ores, retail prices of cut gems, values of metals and minerals. A glossary also is appended, along with useful tables. Numerous clear half-tones and diagrams are interspersed throughout the text.

The binding is strong, the type clear, and the arrangement good.

CORRESPONDENCE.

To the Editor

"Canadian Mining Journal."

Dear sir:—

At the meeting of the Canadian Institute held last month I promised to contribute some comments upon some points raised in the papers presented by Dr. Leith and Mr. Willmott. These remarks would have been incorporated with the discussions in the notes of the proceedings of the Institute, had it not been for the inability on the part of the secretary to furnish me with some of the items from one of these papers, so that it is now too late to have this done.

Both of these papers referred to were extremely interesting, that by Dr. Leith was entitled "The Iron Ore Deposits of Canada," and the other, by Mr. Willmott was on the "Iron Ores of Ontario," and the latter was only presented in part and extempore.

Dr. Leith classified the deposits according to their origin, dividing them into six classes, as follows:—

1st—Magmatic segregation.
2nd—Pegmatite type.
3rd—Lake Superior sedimentary type.
4th—Clinton sedimentary type.
5th—Carbonate type.
6th—Brown ore type.

This mode of classification is very useful, not only to the engineer, who will find himself more at home in making examinations and reports upon the deposits, but also to the experienced miner, who will find it a assistance in laying out his work correctly when endeavoring to win the ore from them.

Now it can readily be understood that, in the enumeration of the iron deposits of a country so vast as Canada, it is hardly possible for any single individual to possess an intimate personal knowledge of them all, and even if he wishes to confine the subject matter of his paper to those which are well known, he must perforce rely to some extent upon the opinions of others, whom he believes to be familiar with the localities in which the deposits occur. It is possible, therefore, owing to this dependence upon the work of others, that the explanation of certain phenomena might be based upon accurate observations, or again, it might be based upon the writings and teachings of persons, whose theories seem to have every appearance of fitting the case in question, or, yet again it might be based upon a

mere guess, in which the particular theory which happens to be the prevailing fashion is followed, whether it be the neptunic or volcanic. In this manner it may occur, quite inadvertently, that we may place statements on record in our writings which we would most assuredly have omitted, had we possessed an intimate personal knowledge of the actual facts of the case.

I might mention one single instance of this, the genetic occurrence of the Atikokan magnetites; these are classed by Dr. Leith under heading No. 2 of his table; this classification is erroneous, and the error can readily be shown, since no deposits afford more simple problems for the observer than these. Had Dr. Leith consulted my paper on "The Atikokan Nickeliferous Pyrrhotite Deposits and their Origin," Vol. IX, of the Proceedings of the Canadian Mining Institute, he would have not been guilty of such a lapsus. But I must excuse him because he told me since that he had forgotten that paper.

Not so easily, however, can I forgive him his statement, or rather I should use the plural and say statements, for I find it repeated several times, in other publications, to the effect that the occurrence and discovery of iron ores on this side of the international boundary in the vicinity of Lake Superior, was disappointing; especially, in speaking of the Animikie iron-bearing rocks, he asserts that, if 200 feet more of this formation had been eroded, the whole of the formation would have totally disappeared. This is a belief that originated with Van Hise, who promulgated this theory, in spite of the fact that he had no direct or personal knowledge of the facts, then Dr. Leith follows in his footsteps, and, last in order comes Mr. Willmott.

Let us consider upon what basis these assertions rest. Merely upon the experience in that portion of the Animikie formation lying in proximity to Loon Lake, on its southern shore, at a distance of about 23 miles from Port Arthur, in a northeasterly direction, and upon the knowledge of the locality adjoining Gunflint Lake to the west, situated about 90 miles southwest of Port Arthur. The former district forms the northerly margin of the iron-bearing rocks, which at that point are only a few feet in thickness, and consequently the hematite found there is in places very shallow. The latter region is the western boundary of our Animikie rocks, which are cut out at that point by the intrusion of a number of different eruptive rocks. Now, what I would ask is, whether a man is justified in judging a formation, such as is found here, over one hundred miles in length, and at many points over twenty miles in width, and making an estimate of its probable value from merely examining the margin, or should he not rather for his opinion on such a large area by considering the formation in toto? The latter is surely the only proper method, and if these gentlemen had taken the occasion to consult my monograph on "The Genesis of the Animikie Iron Range," in the Proceedings of the Canadian Mining Institute, Vol. VI, 1903, pages 243-253, they would have discovered that this formation is much thicker on this side of the boundary line than it is on the other. Dr. Selwyn estimated its thickness to be about 12,000 feet, but we would come nearer to the actual facts if we divide this figure by four, and then it would only be as deep as this in the deeper basins. If this be the case, I fail to see any good reason why we should not find as good iron and as large deposits of hematite ore in our own rocks as are found on the Mesabi or other Lake Superior hematite ranges. Throughout the whole of this series of ranges the rock formation is identically the same, forming, in Pre-Cambrian, or one had preferable call it, Post-Laurentian times, one continuous and uninterrupted rock mass. The fact that the same large deposits of hematite have not been found here as have been opened up on the other side is easily accounted for—we simply have so far neglected to prospect our Animikie rocks: the little, however, that has been done and the results attained thereby should have given any one sufficient encouragement to go down into the deeper basins of this rock, in which it may reasonably be expected that we shall find larger and purer deposits of hematite. I venture to predict that, as soon as much diamond drilling has been done here, as has been done on the Mesabi range alone, both Dr. Leith and Van Hise will doubtless be only too willing to retract the statements they have made about our Animikie range.

Dr. Leith's statements I find more pardonable, because I can easily understand his reluctance to contradict his former mentor, Prof. Van Hise, although I have observed that, as regards the origin of these rocks, their ways are already beginning to diverve, and that Dr. Leith has started travelling upon a road that is somewhat more direct and also more correct. I welcome his company thereon.

Towards Mr. Willmott I hardly think that I can extend so much mercy, because for several years he lived here himself, and for a still longer period had prospecting parties throughout the district. It was, therefore, to be hoped that he would have been too well informed to fall into such glaring errors. I only learned of these erroneous statements upon reading his paper as published in the "Journal," these subjects not having been touched upon in his extempore discourse at the meeting.

What appears to me to be a very grave omission has been made by both these gentlemen, and I cannot rest without alluding to it; for they hardly mention my special big pet, the Mattawin iron range. The reader can well understand my sentiments when I state that this range contains perhaps the largest low grade iron deposits of which we have any knowledge. The figures will speak convincingly enough for themselves. The range commences about twenty miles west of Port Arthur and ends in St. Louis County, Minnesota, thus being nearly 100 miles long. Some of the individual deposits are 500 by 1,000 feet, one 660 by 3,000, and another 1,000 by 10,000 feet, and all of them have a depth of at least 5,000 feet. Many other deposits are found here of a similar size. Now, if my readers will kindly figure out how many million tons of iron ore these three first named deposits alone contain, and how many years they would last the population of Canada, when they were mined and reduced to iron and steel for their use, after having worked out this calculation, they will not consider it so very extraordinary for me to feel somewhat aggrieved at the light-hearted omission made by these two gentlemen who take so much interest in the problems of iron ores.

I can now let Dr. Leith step down from the stand, but I would like, with his kind permission, to devote a little more time to Mr. Willmott.

During almost the whole of last year I was absent from home and in consequence I had perforce to neglect to a great extent the perusal of mining and other journals. A few days ago, however, the November number of "The Canadian Mining Journal" came acci-

dentally into my hands, and upon it my eye was caught by the heading of a paper entitled "The Origin of Deposits of Pyrites," by Mr. A. B. Willmott.

I would ask Mr. Willmott to bear with me while I offer a few corrections as regards the nature and origin of some of the sulphide of iron deposits quoted by him. He attributes the origin of a large number of the pyrite deposits to sedimentation, and refers, for support, to Beck, Kemp and others. Both of these observers, however, classify pyrites deposites according to their different origins, and cite cases of different modes of sedimentation. Mr. Willmott in his paper enumerates a multitude of pyrites deposits, but I fail to find any explanation as to what kind of sedimentation he ascribes their occurrence, although it ought not to have been a task of very great difficulty to deduce some theory as to their origin from the rocks associated with them, from their physical structure and from the often peculiar character of the enclosing rocks.

Mr. Willmott speaks at length of the Michipicoten and surrounding district, he traces the association of the different minerals with the pyrites, he describes also the peculiar shape of the immediate environments, their pond-like shape surrounded by rocks, or the rounded or elongated depressions in which these deposits are found, but in spite of all that he speaks only of sedimentation—what kind of sedimentation, then, does he refer to?

Any person who is acquainted with that country is also well aware that, in both pre and post-Cambrian times there was a period of great volcanic activity, as witness to which we have the vast number of basic rocks, tuffs and granites. With this knowledge to guide us, and from observation of the locations in which these pyrites deposites are found, would it not be reasonable for us to come to the conclusion that some of these pond-like places or rounded depressions are the collars and vents of craters, vents of geysers or fumaroles, such as we can see in several places in this locality, in a beautiful state of preservation. At Steep Rock Lake we find similar pyrites deposits of a high grade limonite and manganese. In the immediate neighborhood we find some of the most beautifully preserved geyser vents that I have ever seen dating from a period so remote. In addition to these geysers, there must also hav been numerous mineral springs carrying various mineral contents in solution, similar to those which we can see occurring to-day in the Yellowstone Park. Now there can be no doubt of the fact that these Steep Rock Lake deposits are produced by mineral springs coming from a subterranean source, and if we connect these deposits with volcanism it would only be a natural inference that the Michipicoten deposits were produced in the same way. But in that district there occur not only iron di-sulphide deposits, but also some very large deposits of pyrrhotite, one of which is especially remarkable for its size and massiveness. The one I refer to is found on locations 223 and 224X, north of Cuthbert Lake, and this deposit no one would surely classify as a sedimentary product—it is as clearly a magmatic segregation product as those in the vicinity of Sudbury, carrying a certain amount of nickel. In addition to this one, there are a number of similar examples that might be quoted.

There is no doubt that the Helen ore is to a large extent an oxidation product, from pyrites and siderite, but these minerals are not of the same age as the Animikie rocks, as has been repeatedly asserted, but date from the time of the greenstone eruptions, which occurred after the Animikie had been laid down.

Mr. Willmott alluded to the 'pyrrhotite" deposits, near the Kaministiquia River, and those near Schreiber, as "pyrites,' and to them he also attributes a sedimentary origin. This opinion is clearly erroneous, for there can be found no truer type of a magmatic differentiation products than these deposits, which are quite numerous in both localities. The pyrites found associated with the Schreiber ore exists only at the surface, consisting, usually, of a shallow layer from about one foot to a foot and a half in thickness, and represents merely a re-arrangement of the molecules from FeS_8 to FeS_2.

Towards the close of his paper he speculates on the origin of this pyrites, arriving, however, at no definite conclusion. He does not know how silica, iron and sulphur were dissolved, now how they were precipitated, but he says that there must have been volcanic activity at that period, but this activity only served to add mechanical sediments to the chemical. Might it not have been expected that the thought would have arisen that these deposits in the Michipicoten district and elsewhere are all the products of volcanism, partly produced by the after action of volcanism and partly as the direct result of the same agency?

Mr. Willmott asks how the silica, iron and sulphur were dissolved and precipitated. Let me ask him, in turn, how the silica, the iron, the copper and other metallic sulphides are carried into the fissures of the rocks, forming veins, or into porous rocks strata, forming impregnations. Do not the geysers and the many hot and cold mineral springs of the Yellowstone Park and of Iceland, and those found throughout Europe and Australia and elsewhere, give us some idea of the manner in which lime, silica, iron and other rock or metallic minerals are dissolved, or are found by us in a state of solution, and are precipitated? And if we picture to our minds the remote periods, with their accompaniment of enormously greater volcanic activity, during which these pyrites and pyrrhotite deposits had their origin, it should be a matter of no great difficulty to realize the manner in which these phenomena occurred.

F. HILLE, M.E.

Port Arthur, April 27, 1908.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.

There is very little to chronicle at the collieries at the present time, a sure sign that all is going well. The mines have got into their summer stride, and some remarkably good outputs have been made. As we forecasted some time ago the mines of No. 2 colliery district have made a record. On the 14th of May, No. 2 colliery had an output of 3,221 tons and No. 9, an output of 1,879, making a total output for one day from one shaft of 5,100 tons. The previous record for this shaft was 4,656 tons. It would be interesting to know whether this is not a world's record. No. 6 colliery is also doing well having reached 1,200 tons on one day this fortnight. No. 10 mine, the Emery, has also the highest output that it has ever made to its credit during the same fortnight, namely 718 tons. We think we are safe in saying that this is the largest output

ever produced from a purely longwall mine in Nova Scotia in one shift. With the exception of No. 3, all the Dominion collieries are on single shift. Another record was an output for all collieries of 15,539 tons on single shift. And yet if one enquires for news around the collieries we are told there is "nothing doing."

The Hub Colliery commenced to hoist coal on the 18th, after a six weeks' rest. During this time the mine has been thoroughly cleaned up; the main deep has been straightened and widened and an electrical endless haulage system installed. Two new electrically driven pumps have also been completed, and extra boilers and compressor plant installed. A new man hoisting engine has also been installed. The main deeps are about a miles under sea beyond high water mark, the coal is dipping at about the same pitch as formerly and maintains the same thickness. The mine has been idle rather longer than was anticipated, but from now on it should give a good account of itself.

At No. 6 Colliery a powerful new haulage engine is being put down, the main deep is being double tracked and put into shape for endless haulage, when the output is capable of being materially increased. The fact that this mine is producing somewhat like 20,000 tons a month, all of which is very readily absorbed is a sufficient commentary on the commercial qualities of this coal.

The Brooklyn Daily Eagle prints very complimentary remarks about Nova Scotia's possibilities as a country of mining investments. This paper says: "It may be said, without making use of extravagant language, that there is not a country upon the face of the earth which offers such absolute safe returns upon mining investments as the Province of Nova Scotia." It makes a statement also which we think is a little remarkable, namely, that the Dominion Coal Company has proved that its mines are capable of an output of 3,500,000 tons per year for a thousand years! Not that this need worry any Nova Scotian, for a thousand years is a long time. It should comfort Steel and Coal shareholders a little. The Brooklyn paper refers to Nova Scotia's gypsum exports, and we think that in her stones will be found the greatest wealth of Nova Scotia. There is in this province gypsum, marble, porphry, syenite, fine sandstones, jade, talc, mica, coal and iron. These we think will prove more precious than gold and silver. We hope the Brooklyn Eagle is right in its estimate of Nova Scotia's possibilities, and as to Dominion Coal, well, in a thousand years we shall be where steel will cease from troubling and coal will be at rest.

ONTARIO.

Cobalt.

The shipments from the camp for the week ending May 16, amounted to 447 tons. The shippers were as follows: Cobalt Lake, Cobalt Central, Kerr Lake, La Rose, McKinley-Darragh, Nipissing, Nova Scotia, O'Brien, Right of Way, T. & H. B., Temiskaming, and King Edward.

Nipissing.—A shaft is being sunk on a vein in the northeast corner of the town of Cobalt. A diamond drill is also in operation close by.

At a meeting of the directors of the Nipissing Mines Company (the holding company), E. P. Earle was re-elected president, L. B. Kendall, vice-president and John Josten, treasurer. The office of the company has been moved to 71 Broadway, New York.

Right of Way.—On May 19, thirty tons of high grade ore were shipped to Copper Cliff.

Seventy-five men are now employed in the various workings.

Lawson.—A small force of men are now at work trenching.

Cobalt Central.—The Standard Cobalt Mines Company, one of the subsidiary companies of the Cobalt Central, has leased 40 acres adjoining the Big Pete on the south. The lease, which is from the Bailey Cobalt, is on the basis of 50 per cent. royalty. The period is for two years with an option for three additional years.

Youngstown Cobalt.—A small steam plant has been purchased and will be installed on the property of the company, northwest of Sasagina Lake.

T. & H. B.—No. 2 level east, is showing up some good ore. On driving east on the cobalt vein, the ore is beginning to show native silver. There was no silver at all on the surface, in this vein.

Chambers-Ferland.—Arrangements have been made by this company to obtain air supply to operate drills, from the La Rose Company. Pipe lines are being laid from the La Rose to the No. 1 and No. 2 shafts. A careful sampling of the vein in the bottom of the No. 1 shaft, about 45 feet in depth, gave a value of 5,100 ounces of silver.

Casey Cobalt.—Twenty-five men are at work here. A station is now being cut at the 165 foot level.

Silver Leaf.—In the north face of the shaft, at a depth of 140 feet, a new vein running at right angles to the main vein, has been encountered. The values in the main vein are as high as ever and the outlook is encouraging.

The impression got abroad that this mine was being worked on a lease, but the facts are these: instead of receiving a salary, the manager, Mr. Symmes, receives 10 per cent. of the net proceeds and out of this he pays the mine superintendent's salary.

Shamrock.—Half a twelve drill compressor and a sixty and eighty h. p. boiler will be installed at once and active work begun under Mr. McPherson, who will have charge.

Little Nipissing.—A car of ore will be shipped in a few days from the Peterson Lake lease of this company. Arrangements have been made to secure an air supply for operating drills and a hoist from the Nipissing Company. Active work will be started as soon as the connections are made. The shaft which is now down 45 feet, is being timbered and a water tight concrete cellar is being made. There is every prospect of this mine becoming one of the important shippers in a short time.

O'Brien.—Work has been started cleaning away for the new concentrator to be erected. This will cost $125,000 and will be capable of treating 100 to 150 tons a day.

King Edward.—A ten stamp mill has been ordered from the Allis Chalmers Bullock Company. This is for the concentrating plant.

Crown Reserve.—At a meeting of the directors of this company, Mr. Samuel Cohen was appointed general manager. Mr. Cohen, who had a wide experience in the Cobalt district, has been in charge of the development of the property since October. A extensive system of development has been planned. The working shaft, which is now down 50 feet on a stringer from the main vein, which carries silver and cobalt values, will be sunk to 100 feet. The main vein will be developed by a cross cut run from the working shaft at this level. Mr. Cohen expects to develop the property by a system of exploration tunnels. The main tunnel will be 1,500 feet long, extending east from the shaft and with cross tunnels at intervals of 500 feet.

The ore in the original working is wonderfully rich. Fifty pounds taken from the bottom of the open cut and smelted at the Silver Queen, gave 38½ pounds of silver, 940 fine. A 20 ton car of ore is now being sampled by Ledoux & Company. The refining of the nuggets has not been completed but the ore will run between nine and ten thousand ounces silver to the ton or approximately $90,000 to the car. After being sampled by

Ledoux & Company the ore will be shipped to Delora for treatment.

An interim dividend of 4 per cent. on the capital stock, payable July 1st, has been declared. The stock outstanding is $1,750,000.

Montreal River District.

The Gates property, James township, has been sold to a Detroit syndicate. Mr. Tom Fee of Cobalt is now on the property laying out the plans for development work.

Holden Property.

A promising vein of calcite and copper with small stringers of aplite carrying high silver values, has been encountered in a drift at the 90 foot level. This claim is in Tudhope township.

The righteous indignation of the better class of prospectors and miners in the Montreal River district, has been aroused by the exaggerated and inaccurate statements published in the local paper. Apparently no effort has been made by the editor to confirm the truth or even the probability of a greater part of his "news items."

The development of this district will largely depend on the result of this season's prospecting and development and while outside capital is badly needed there is no room for a wild-cat boom or wild-cat methods of advertising. The owners of properties and the prospectors now in the field are beginning the summer's work with quiet confidence that legitimate development of the rich prospects will make a producing camp of the district. Outside capital undoubtedly is needed and should be secured; but it is far more important that legitimate mining men be attracted and induced to undertake the intelligent development of the district in a practical way, and such men are interested and attracted by sane, attractive, and conservative statements. There is plenty of real news. Interesting stories and news items may be had from almost anyone of the hundreds of men who know the country and are working for its best interests.

Temagami.

Active prospecting and development has been started on the Old Abe property situated one mile north of Temagami station. The three forty-acre claims which constitute the holdings of this company, were prospected last summer with very promising results.

ALBERTA.

Coleman.

The miners in the collieries of the International Coal and Coke Company's mines, struck owing to a dispute about pillar drawing. The men have a contract rate for this work, but the company wished to introduce day labor. The men were only idle for two days and resumed work pending the sitting of the District Grievance Committee, when the whole matter will be investigated, and it is thought that it will be finally settled without an arbitration board being asked for.

Frank.

An examination of candidates for Fireboss' certificates was held in this town last week. Six candidates presented themselves for examination. The examination board consisted of the two mine inspectors for the province and one member representing the mine owners and a fourth member representing the miners.

Although practically no work has been done at the mine since Christmas, the outlook for the future is much brighter. The company has been reorganized and Mr. H. Gebo has undertaken the general management of the concern, with Mr. S. McVicar as mine manager, and C. Chesnut as pit boss.

Mr. G. C. Rochfort, book-keeper with the old company, has been elected as secretary-treasurer, with Mr. G. S. Silverman as travelling sales agent.

The old slope east of the town has to be pumped out. This slope has not been worked for a number of years, but it is now intended to reopen it.

A force of men are at work repairing the main tunnel and doing other preliminary work with a view to an immediate resumption of work.

Mr. Gebo has taken a large contract to supply coal to a Spokane firm and at present extensive alterations are being made on the screening plant so that the requirements of the contract can be fulfilled.

Strathcona.

The case of 21 miners versus the Strathcona Coal Company came up in the District Court before his honor, Judge Taylor. Some time ago the company made an agreement with the men after an Arbitration Board under the Lemieux Act had investigated a dispute between the said parties. Since then the company entered into a new agreement for a smaller wage with three of the men on behalf of their fellow-workers without complying with the requirements of the Lemieux Act.

The judge held that the three men who made this new agreement must abide by it, but the agreement was not binding on the other workmen.

The United Mine Workers of America has taken up the question and will appeal from the decision of the judge with respect to the three men. It is also understood that they will enter an action in the Supreme Court against the Strathcona Coal Company for $20,000 damages for violation of their agreement.

Lethbridge.

No. 3 shaft of the Alberta Railway & Irrigation Company does not average more than three days per week. There is very little improvement to be looked for until dealers begin stocking up coal for the fall again.

The new shaft situated a short distance from the town is being rapidly pushed ahead. Mr. Robert Livingstone who has charge of the construction work at this shaft, resigns his position with the company at the end of the current month. Mr. Livingstone has been appointed by the Provincial Government to the position of mine inspector for the Lethbridge and the surrounding districts. Mr. Livingstone, though a comparatively young man, has had a long experience in mining and has worked himself up from the ranks. He has had considerable experience in the States and has been with the Alberta Railway and Irrigation Company here for over seven years. He has also had considerable experience in the Edmonton coal field where he was manager for the Edmonton Standard Coal Company.

BRITISH COLUMBIA.

Phoenix.

The business interests of the Boundary district are in good spirits just now over the resumption of work by the British Columbia Copper Company after their long shut-down. Owing to the fact that the fixed charges in connection with the Copper Company's plant were quite heavy and also owing to the favorable factor, the low cost of production in the Boundary, due to a spirit of friendly rivalry for low costs that has existed among the managers of the big copper producers of the Boundary, the British Columbia Copper Company has found that it is more

economical for them to operate even with copper at its present low price than to remain in idleness. While the British Columbia Copper Company cannot make copper as cheaply as the Granby, yet, they are a close second to that company in cost of production. The Granby can make copper for about 10 cents per pound and with good management the Copper Company should be able to make it for 11 or 11½ cents per pound, this to include cost of selling, etc. The plant of the Copper Company and work at the mines are being got into form as rapidly as good practice warrants and within 25 or 30 days they will be able to ship 2,000 tons of ore per day from the mine and turn out 1,500,000 pounds of blister copper from the smelter. They will then be employing between 400 and 500 men at the mines and 200 men at the smelter. The new 35-drill Rand compressor is receiving the finishing touches and will soon be available for addition to the air supply.

As the British Columbia Copper Company is in a position to treat ore from the Snowshoe mine to advantage and was doing so at the time they closed down last fall, it is stated that the Snowshoe will shortly be opened up by the Consolidated Company and shipments made on a large scale to the British Columbia Copper Company smelter. Should this come about at an early moment, and with the likelihood of the Dominion Copper Company finding it more economical to work than to lie idle, the Boundary district will exhibit some of its old time liveli-

300 ft. level Old Ironsides, Phœnix, B.C.

ness. The plant of the Dominion Copper Company is being kept in readiness for immediate resumption of work but no word has been received by the management from headquarters as to going back to work, so far.

Shipments from the Granby mines for the week ending May 16th amounted to 24,309 tons and their total for the year to date is 402,354 tons. With seven furnaces working at the smelter they treated 22,402 tons of ore which makes the amounted smelted up to date 392,494 tons. Diamond drill prospecting is being continued on the property. During the last four years the Granby Company has drilled 29,117 feet of diamond drill holes in the hill, or over six miles of work. Diamond drilling has been found economical development in the Granby mines and has given good results.

The Crescent mine at Skylark camp shipped a thirty-ton car of ore to the Trail smelter during the week.

The Greenwood prospecting tunnel proposition keeps bobbing up every now and then and it looks as though work might be started. The company has been, or is to be, capitalized for $5,000,000 in $1 shares, which looks a little damp to the cursory observer. The promoters may be able to see their way clear to make a paying proposition out of their tunnel but from the information one can gather it will be more of a speculation as to the encountering of the high grade lodes that may be on its line rather than an industrial enterprise for the economical handling of Phoenix ore.

In the Boundary and all through the Kootenays there are mining propositions that are used as a basis for the sale of stock and intending investors in legitimate mining propositions must make strict inquiry as to the merits of any company they are going to put money into, for the risks with which the best mining ventures are fraught, are hazard enough without banking on luminous but hazy reports from wild-cats and knife-blade ledges of ore, probably of high grade, that cannot be mined at anywhere near a profit, although it may assay into the hundreds.

Rossland.

Prospecting in the South Belt and work on the good showings they have in that district are being executed with some of the zeal and hope of the earlier days of the camp. Mining men are keeping in close touch with work in that part of the camp and if results obtained during the next few months warrant it considerable development, on a larger scale than at present, will be undertaken. The Monday claim has been leased by John Brokenshire and associates, Mr. Brokenshire having sold out his interest in the Blue Bird lease at a good profit. The Monday is near the Blue Bird and a little work on the property may uncover the continuation of the Blue Bird ledge. The Spitzee, which the Le Roi Company had under lease for a while has again been leased and work will be started right away. The Spitzee is having a lot of ups and downs but may surprise even those who think it will prove a good property some of these days.

The shaft of the Centre Star is now down to the fifteenth level, 2,100 feet from the collar. In consequence of the encouraging showings that have been met with at depth in the Star the shaft will be sunk still deeper in the near future. The rich gold ore still continues to be found and mined in the lower levels of the War Eagle and work on the Iron Mask and Idaho portions of the Consolidated Company's property is giving satisfactory results.

The Le Roi, Josie and Giant California mines are prosecuting work with their usual vigor and good results are being obtained for every foot of work done.

The Blue Bird has shipped another 20-ton car of good grade ore to the Trail smelter. The combined output of the camp continues to average 5,000 tons per week and the receipts of ore at Trail smelter run about 6,500 tons per week, including ore from the Snowstorm (Idaho), First Thought (Wash.), North Star, Richmond, Rambler-Cariboo, Vancouver and Reco.

One of the flumes bringing water to the city burst recently and the escaping water carried away the wash and laid bare a hitherto unknown ledge of mineralized matter. One of the miners who appeared on the scene recognized that it might prove of value and staked a claim upon it.

M. R. Galush, managing director of the Jumbo mine, Spokane, states that they will put a small force of men to work on the Jumbo at an early moment, which will be augmented as the showing made warrants. Mr. E. L. Tate, one of the large stockholders in the Cliff mine, which is one of the most promising properties in the camp, is in Rossland from Spokane and says that if the interests in the Cliff can be got into harmony something will be done with that property this season.

Nelson.

The Canada Zinc Smelting Company of Nelson will begin operation June 1st. The capacity of the plant for the present time will be twenty tons per day. The machinery will be elec

trically operated and will require about 1,00 horse power which will be developed from power derived from the high voltage lines of the West Kootenay Power & Light Company.

It is reported that the ore body they have been prospecting for in the Ymir mine has been located, but the management is very quiet about the strike. Spokane men are expected up to examine the Yukon in a few days.

At the Giant mine, near Golden, an up-to-date Elmore oil process of concentration has been installed. It is expected that this improved process will be far ahead of the first plants installed.

The old ledge has been encountered on the Granite Poorman near here. The lessees have been making a good profit from ore taken from a new ledge and the strike now made will prove a good one. The car of ore shipped from the Slocan Sovereign, March 23rd, returned 90 ounces silver and 60 per cent. lead.

It is the general opinion here that the lead bounty will be extended all right, although nothing has been heard as yet regarding the matter. One reason advanced, and a good one, is that there is yet enough of the grant unused to run for a further period of six years, at the rate it was used during the last couple of years.

GENERAL MINING NEWS

NOVA SCOTIA.

Halifax.—The Lake View gold mine, at Waverly, has been sold by Mr. A. A. Hayward, to Mr. J. B. Woodworth, the discoverer of the Nova Scotia Cobalt mine. Mr. Woodworth represents a small syndicate of which Mr. O'Brien of the O'Brien Cobalt mine, is a member. The Lake View is a well-equipped mine. A considerable quantity of high grade gold ore is blocked out and some thousands of feet of development have been finished. It has lain idle for some years.

Mr. W. J. Prisk, formerly manager of the Dominion Antimony mine, West Gore, is now in charge of the Eagle Mining Company's property at Renfrew.

There are rumors of an English syndicate being formed to operate a group of Nova Scotia's gold mines. Definite news has not yet been received, but the concern is reported to be a responsible and large one.

Sydney.—Fire broke out on the evening of May 19th in the pipe shop of the Dominion Iron and Steel plant. The building was destroyed. The estimate loss is small and is covered by insurance.

ONTARIO.

Madoc.—Talc shipments from the Henderson talc mine are to be made within a few days. It is announced that the output of the mine will be largely increased.

Cobalt.—The main shaft of the Nova Scotia mine is down 160. The drifts are in good ore. About 60 men are employed.

The Foster mine has removed a part of its underground force with the intention of devoting more time and energy to prospecting the remainder of its territory. Only a small proportion of the Foster lot has been worked.

The Cobalt Central has leased the Bailey property. An arrangement has been made whereby the Bailey Company will receive 50 per cent. of the net production.

Sault Ste. Marie.—The power house of the Lake Superior Power Company was destroyed by fire on the morning of May 18. The estimated loss is $300,000, fully covered by insurance.

BRITISH COLUMBIA.

Fernie.—John Cattell, a machinist in the employ of the Crow's Nest Pass Coal Company at Coal Creek, was killed on May 6. In some manner he was caught and dragged underneath a mine locomotive. The engine and eight cars passed over him, mangling the body fearfully.

Nelson.—The Queen mine at Salmo was sold on May 4th to an American syndicate. The purchasers are residents of the state of Wisconsin. The mine is to be worked at once. The price paid is reported to be $175,000. Of this $50,000 is to be paid cash down, the remainder in 30 months. The terms of purchase stipulate that work shall be continuous.

Rossland.—The second general meeting of the western branch of the Canadian Mining Institute was held in Rossland on May 14. The morning and afternoon sessions were attended by about fifty members. In the evening a smoker was held at the Rossland Club. Trail, Nelson, Grand Forks, Phoenix, Vancouver, Victoria and Northport were represented. Professors Dresser and Porter of McGill University were present. Mr. A. B. W. Hodges occupied the chair. The local council was increased. A resolution was passed requesting the Provincial Government to make a grant of money towards defraying the expenses of the British delegates who are to visit British Columbia next fall.

On May 15, the visitors were shown through the principal Rossland mines.

Phoenix.—There is rejoicing in Phoenix. The British Columbia Copper Company's mines and smelter are operating again. On May 6, work was started at the Mother Lode mine, Deadwood camp, and at the Emma and Oro Denoro mines, Summit camp. The smelter also is being got ready. The three furnaces will be blown in as soon as the ore bins are full. There is a large supply of coke on hand. The company has a contract for treating the ore from the Consolidated Company's Snowshoe mine. This will mean an addition to the payroll. It is hoped that the smelter will be able to handle about 2,000 tons of ore per day. During the first ten months of 1907, the British Columbia Copper mines shipped 242,788 tons of ore. The individual mines contributed to this total thus:—Mother Lode, 208,321 tons; Emma, 18,274 tons; Oro Denoro, 14,481 tons; B. C. mine, 1,712 tons.

Greenwood.—The plans for the long Greenwood Phoenix tunnel are maturing. Work will be commenced before the first of June. When driven a mile, starting from Greenwood, it will tap seven mining properties, giving natural drainage and doing away with haulage and hoisting.

Victoria.—Mr. W. W. Leach of the Geological Survey, left Victoria for the Bulkley Valley in the Skeena river district. Mr. Leach will be accompanied by a party of six. He will return in October.

Atlin.—The Otter Creek Hydraulic Company will begin washing as early as weather permits. Messrs. Jamieson and Maluin are in charge.

YUKON.

Dawson.—Reports indicate that eighteen dredges will be operated in the Klondike, Forty Mile and Stewart River districts this season. The first electrical conveyor ever installed is to be used by the Goggenheims.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The South Wales and Monmouthshire coal owners have adopted the recommendation of the Royal Commissioners on Mines with respect to establishing rescue stations and definite steps have now been taken to proceed with the necessary building. The first station will be constructed at Aberaman, in the Aberdare valley, where officials and others will be trained in rescue work. The building will be equipped with Fleuss' apparatus and other appliances.

Mr. Richard A. S. Redmayne, M.Sc. F.G.S. has been appointed Chief Inspector of Mines. Mr. Redmayne, after a lengthy practical experience in responsible positions, has been professor of mining at Birmingham University since 1902, and is the author of several books on mining.

Lord Ardwell has given his decision in regard to miners' wages in Scotland to the effect that a reduction of 6¼ per cent. be made on the 1888 basis, which reduces present wages to 81¼ per cent.

FRANCE.

The zinc works of Mortagne are developing rapidly. After working for about two years and a half the production attained 8,500 tonnes in 1907, with six furnaces and 240large retorts per furnace. The total zinc productions for last year was 49,000 tonnes and an increase of a few more thousand tonnes will supply the home demand for metallic zinc.

AUSTRIA-HUNGARY.

The Hungarian coal industry is very active owing to the growing demand and the scarcity of labor has resulted in increased wages and improved housing conditions. New shafts are being put down in several districts and prospecting is being energetically carried on.

RUSSIA.

American capitalists are endeavoring to secure control of the platinum industry of the Urals. Negotiations are on foot for the purchase by American interests of the Tagil factories, the Nizhe Pavdinsk properties of Vorobieff and others.

SOUTH AFRICA.

A Department of Mines and Works has been established in Southern Rhodesia, with Mr. E. W. S. Montague as secretary.

There are now 70 tube-mills in operation in the Transvaal which have largely increased the output. At the Luipaards Vlei Estate mine the duty per stamp per 24 hours is now 9.12 tons.

JAPAN.

The abundance of gold to be found in Satsuma has of late attracted the attention of capitalists. There are altogether 197 gold mines, or gold producing districts, many of which have been worked for a long time by hand digging on a small scale. The yield is roughly estimated at 3,000,000 yen a year. Modern methods are now being introduced including water power electricity for the operation of machinery.

AUSTRALASIA.

An important discovery of nitrate of soda has been made on the Grampas station in the Northern region of South Australia. This mineral is found as in Pern beneath a cap of guano. Samples show 24 to 29 per cent. of nitrate of ammonia.

A Geological Survey bulletin on the Great Fitzroy mine, Queensland, places the quantity of ore yielding gold, copper and silver in sight as over 600,000 tons.

A Sydney capitalist has determined to test the Gulgong district, New South Wales, where there were formerly rich alluvial diggings, for deep mining. He purchased several leases and is installing a plant.

Miners are prospecting the ridges northwest of Puranga station, New South Wales, for opal. Twelve years since opal was extracted in this neighborhood, but operations were not continued.

UNITED STATES.

Shipments of anthracite coal from Pennsylvania during April amounted to 5,987,221 tons, making a total of 20,875,474 tons since January 1st, as against 20,966,063 tons for the corresponding period last year.

The iron ore industry of the Lake Superior iron region continues depressed, and production is much restricted. Both the Chapin and Arragow mines of the United States Steel Sorporation, the two largest producers on the Menominee range, are being worked on half-time. There are scarcely a thousand men on the pay rolls, the normal force being about 1,600.

The large mines of Butte district, Montana, are gradually resuming the usual production, and there are few evidences of depression. Much attention is being given by operators to the reduction of the cost of production, and it is expected that several of the amalgamated properties will this year produce copper at a record low cost. The copper production of Butte for April was 21,530,250 pounds, being the largest since July last, when the output was 27,157,300 pounds.

The Copper River & Northwestern Railroad in Alaska is being pushed to completion. About 1,500 men are working on construction. The road is expected to reach the Catalla coal fields this year, and the Alaska Central, also under construction, will probably tap the Matanuska coal fields next season.

MEXICO.

The American Smelting & Refining Company will shortly blow in their smelter near Chihuahua. They expect to get about 15,000 tons of ore monthly from the Santa Sulalia district.

A strike of rich silver ore in the Bien Venido mine at Boru quillas in the Roncesvalles district, Chihuahua, has arroused great interest. Four tons of the ore netted $4,000. Many locations in the neighborhood have been taken up.

COMPANY REPORTS.

The Report of the Tilt Cove Copper Company, Limited, for the year ended December 31st, 1907:—The report of the Committee of Management, presented to the shareholders at the twentieth ordinary general meeting, held on May 14, at No. 9 Queen street place, London, shows, in the Profit and Loss account, a credit balance of £23,587 13s. 9d.

Copies of the reports and accounts presented by the Cape Copper Company at their last general meeting, embracing a description of the progress and result of their operations on this company's property for the twelve months ending August 31st, 1907, were sent out to each shareholder on the 28th of November, 1907. The Cape Copper Company's Tilt Cove establishment audited accounts for the year ending December 31st, 1907, are appended. They show that the mines made a gross profit of £58,609 11s. 5d., leaving, after charging the account with the rent (representing the interest on the debentures), prospecting

costs, management, etc., a net profit of £51,034 14s. 11d. The balance of profit thus remaining has been dealt with as follows: £25,517 7s. 5d., has been retained by the Cape Copper Company, and £25,517 7s. 6d. has been received by this company as its moiety of profit, as provided for in the agreement with the Cape Copper Company.

Although a profit of £51,034 14s. 11d. is shown on the Establishment account, that result is arrived at after the absorption of £38 2s. 4d., an increase in the amount retained for working capital, and this amount has been added to the capital expenditure on the one side of the account, and to the reserve for depreciation on the other, as heretofore.

Out of the available profit of £27,098 3s. 8d., £1,374 5s. 9d. has been paid in income tax, and interim dividend of 2s. 9d. per share was paid on December 3rd, 1907, and the committee now recommend a final dividend of 2s. 3d. per share, making a total distribution of 5s. per share, or 12½ per cent. for the year, leaving the sum of £3,473 17s. 11d. to be carried forward to the next account.

COMPANY NOTES.

The dividend of the International Coal and Coke Company has been reduced from the annual rate of eight per cent. to five per cent. Dividends were begun on the first day of February, 1907. The directors had hoped to wipe out the outstanding obligation of $200,000 by disposing of treasury stock. The uncertain and disturbed condition of the market made it impossible to do this. Hence the reduction in the dividend rate. The difference is to be applied to the liquidation of the indebtedness. The next quarterly dividend will be at the rate of one and one-quarter per cent.

The annual meeting of the Silver Leaf Mining Company, Limited, will be held at McConkey's, at 10 a.m. on June 2nd.

STATISTICS AND RETURNS.

The output of the Crow's Nest Pass collieries for the week ending May 22 was 10,950 tons, or a daily average of 1,825 tons.

The Crow's Nest Pass Coal Company, Limited, report the output of the collieries for the week ending May 15th, as 19,385 tons, a daily average of 3,231 tons.

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1st to date:

	Week end. May 16.	Since Jan. 1.
Buffalo	.....	563,810
Coniagas	.....	830,910
Cobalt Lake	65,845	246,455
Crown Reserve	.....	40,000
Cobalt Central	49,200	156,380
City of Cobalt	.....	338,600
Drummond	.....	92,340
Foster	.....	238,400
Kerr Lake	61,960	392,270
King Edward	.....	127,240
La Rose	80,000	1,981,652
McKinley	60,000	1,243,900
Nipissing	133,020	1,316,920
Nova Scotia	106,765	227,555
Nancy Helen	.....	140,420
O'Brien	63,800	1,826,370
Right of Way	60,500	181,180
Provincial	.....	143,210
Standard	.....	39,730
Silver Queen	.....	524,200
Silver Cliff	.....	52,000
Silver Leaf	.....	132,800
Townsite	.....	85,100
Temiskaming & H. B.	60,000	599,000
Temiskaming	88,140	325,390
Trethewey	.....	679,916
Watts	66,000	180,430

The total shipments for the week were 895,230 pounds, or 447 tons. The total shipments from January 1st to date are 12,304,448 pounds, or 6,152 tons.

Following are the weekly shipments from Cobalt camp, and those from January 1st, to date:

	Week end. May 9.	Since Jan. 1.
Buffalo	46,290	563,810
Foster	69,800	238,400
La Rose	40,000	1,901,652
McKinley	60,000	1,183,900
Nipissing	122,240	1,230,870
O'Brien	127,500	1,763,070
Right of Way	60,470	120,680

The total shipments for the week were 526,300 pounds, or 263 tons.

The coal shipments of the Nova Scotia Steel and Coal Company for the four months are as follows:

Shipments, April, 1908	38,000
Shipments, April, 1907	33,450
Increase, April, 1908.	4,550
Shipments, 4 months, 1908	155,737
Shipments, 4 months, 1907	120,279
Increase, 4 months, 1908	35,458

BRITISH COLUMBIA SHIPMENTS.

Following are the shipments for the week ended May 2nd, and year to date:

Boundary shipments—

	Week	Year
Granby	19,942	354,472
Other mines	.....	462
Total	19,942	354,934

Rossland shipments—

Total	6,076	96,847

Slocan Kootenay shipments—

Total	1,086	37,834

The total shipments for the past week were 27,104 and for the year to date 489,615 tons.

Granby Smelter receipts—

Granby	19,942	354,472

Consolidated Company's receipts—

Total	5,006	93,008

Le Roi Smelter receipts—

Total	2,359	28,776

The total receipts at the various smelters for the past week were 27,307 tons and for the year to date 381,986 tons.

Following are the shipments for the week ended May 9th, and the year to date:

	Week	Year
Boundary shipments—		
Total	23,203	278,137
Rosland shipments—		
Total	5,589	102,436
Slocan-Kootenay shipments—		
Total	1,110	38,944

The total shipments for the past week were 29,902 and for the year to date 519,517 tons.

Granby Smelter receipts—		
Granby	23,173	377,645
Consolidated Company's receipts—		
Total	6,308	99,316
Le Roi Smelter receipts—		
Total	1,346	30,122

The total receipts at the various smelters for the past week were 30,827 tons and for the year to date 512,813 tons.

Following are the shipments for the week ending May 16th and the year to date:

	Week	Year
Boundary shipments—		
Mine		
Granby	24,309	401,954
Other mines		492
Total	24,309	402,446
Rossland shipments—		
Centre Star	3,744	65,733
Le Roi	1,518	29,949
Le Roi No. 2	508	12,024
Bluebird	53	53
Other mines		500
Total	5,823	108,259
Slocan-Kootenay shipments—		
St. Eugene	251	8,649
Whitewater, milled	280	5,460
Poorman, milled	250	4,100
Queen, milled	185	3,505
Second Relief, milled	145	1,955
North Star	30	1,162
Richmond Eureka	86	635
Rambler Cariboo	43	545
Vancouver	47	501
Ruby	40	181
Slocan Star	65	128
Granite	31	100
Other mines		13,476
Total	1,453	40,397

The total shipments for the past week were 31,585 and for the year to date 551,102 tons.

Granby smelter receipts—		
Granby	24,309	401,954
Consolidated Company's receipts—		
Total	5,801	105,117
Le Roi Smelter receipts—		
Le Roi	1,518	29,929
First Thought	313	1,709
Other mines		235
Total	1,841	31,953

The total receipts at the various smelters for the past week were 31,951 tons and for the year to date 544,754 tons.

Messrs. L. Vogelstein and Company of New York, report the following figures of German consumption of foreign copper for the period January to March, 1908:—

	Tons.
Imports of copper	44,914
Exports of copper	2,084
Consumption of copper	42,830

Of the above quantity 41,999 tons were imported from the United States. The consumption for the same period in 1907 was 24,393 tons.

MARKET REPORTS.

Coke.

May 22—Connellsville coke, f.o.b. ovens—
Furnace coke, prompt, $1.55 to $1.65.
Foundry coke, prompt, $2.10 to $2.25.

Pig Iron.

May 22, Pittsburg—
No. 2 foundry, $15.40 to $15.65.
Bessemer, $16.90 to $17.15.
Basic, $15.90 to $16.15.
Malleable, $15.90 to $16.40.
Southern No. 2, $16.40 to $16.90.

Other Metals.

May 22—
Tin, Straits, 29.55 cents.
Copper, prime lake, 13 cents.
Lake, arsenical brands, 12.85 to 12.95 cents.
Electrolytic copper, 12.85 to 12.90 cents.
Sheet copper, 17 cents.
Copper wire, 14.75 cents.
Lead, 4.35 cents.
Spelter, 4.65 cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.75 cents.
Aluminium, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $23 to $25.50 per ounce.
Bismuth, $1.75 per pound.
Quicksilver, $45 per 75 pound flask.

Silver Prices.

	New York. Cents.	London. Pence.
May 11	52½	24 3-16
May 12	52¼	24 1-16
May 13	52⅜	24⅛
May 14	52⅜	24¼
May 15	52½	24 3-16
May 16	52⅝	24¼
May 18	52⅞	24⅜
May 19	52⅞	24⅜
May 20	53⅛	24½
May 21	53½	24 11-16
May 22	53⅜	24 13-16
May 23	53	24 7-16

MARKET NOTES.

Steel prices are not to be reduced. The manufacturers have agreed to sustain the prices now current.

Of late the copper market has strengthened materially. American buying has induced renewed activity in Europe. Apparently there is little doubt that the tide has turned. Orders are being placed rapidly and the whole situation has brightened

The Canadian Bank of Commerce

HEAD OFFICE, TORONTO

Amatite ROOFING

IF you had a sample of Amatite in your hand you would see in an instant why it needs no painting or coating to keep it waterproof.

It has a rough surface of *real mineral matter* on the weather side. It is evident to anyone that it is no more necessary to paint such a surface than it is necessary to paint a stone wall. Stone needs no paint; neither does Amatite. It is strong enough in itself to bear the brunt of rain and wind and sun without a protective coat of paint.

To paint Amatite would be a waste of time and trouble.

Amatite will last for many years without any care whatever. It is made to be *trouble proof* as well as *weather proof*.

A roofing that consists of smooth materials, made to receive a heavy coating of paint, is not a roofing at all—the paint is the real roof.

If you are told that certain roofings don't need painting when first laid, don't be deceived into thinking that they are like Amatite. The first coat of paint has been applied at the factory—that's all, and it will wear off in a little while and require renewal.

No paint is good enough to make a durable roof; a thick layer of pitch, faced with a real mineral surface, is far better *and that means Amatite.*

Free Sample and Booklet

A Free Sample with Booklet will be sent on request to our nearest office.

PATERSON MANUFACTURING CO., Ltd.
TORONTO MONTREAL WINNIPEG ST. JOHN, N.B. HALIFAX, N.S.

Machinery for Sale at a Bargain

1 Corlis Engine, 16" x 36", with separate condenser. In good condition. Completely overhauled six months ago.

1 Internally Fired Scotch Boiler, about 86" dia. x 18' 0" long. Two furnaces, 33" dia. x 6' 0" long. 136 tubes, 10' 0" long, 3" dia., about 200 H.P.

2 30 K.W., 110-v. D.C. Generators, 800 r.p.m., multipolar, compound wound, complete with pulleys. In excellent condition.

1 60 K.W., 250-v. D.C. Generator, 700 r.p.m., 6-pole compound wound. This machine is also in first-class condition.

1 Duplex Pump (Worthington), 9" x 5¼" x 10". In good condition.

1 Pump (Union Steam Pump Co.), steam cyiinder, 5 1/8" dia., 3 5/8" stroke. Pump cylinder 8" dia.

2 Six-ton, 19-ft. Jib Cranes (steel frame). In good condition.

1 5-ton, 17-ft. Jib Crane (steel frame), in good condition.

1 Portable Key-way Slotter (Morton Mfg. Co.). In first-class condition, scarcely used.
Also some lathes, shapers, &c.

All the above have been in use until recently and can be put into service immediately. They will be sold either singly or "en bloc." Apply to THE CANADIAN LOCOMOTIVE COMPANY, LIMITED, KINGSTON, ONT.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLAR

Provinctal Geologist of Ontario; formeely Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

For Business Buildings

The only cleanly, the only fire-proof ceiling.—the ceiling that says the last word in decorative beauty,—the ceiling that shows no seams—that will outlast the building itself

PEDLAR
ART STEEL CEILINGS

Cost no more than the common sort, but look thrice as fine. Over 2,000 designs, to suit any store or structure. Side-walls to match. See our newest designs—nothing like them in Canada, either in beauty or variety.

Request the free book that shows the whole ceiling story. Send for it to-day. 210

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

The Latest Book on the Electric Furnace

Electric Smelting is a subject of increasing importance to Canadian Engineers and this work contains a clear and connected account of the principle on which electric furnaces are constructed, the uses to which they can be put and the more important details of their construction.

The Electric Furnace

Its Evolution, Theory and Practice

By Alfred Stansfield, D. Sc., A.R.S.M.

Professor of Metallurgy, McGill University

208 Pages Fully Illustrated Price $2.00

The rapid growth of the Electric Furnace makes it increasingly difficult for the metallurgist to keep in touch with its recent devolopments. A few years ago it was a scientific curiosity, but now it threatens to rival the Bessemer converter, the open-hearth steel furnace, and even the blast furnace itself. All Orders for Copies should be addressed to

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

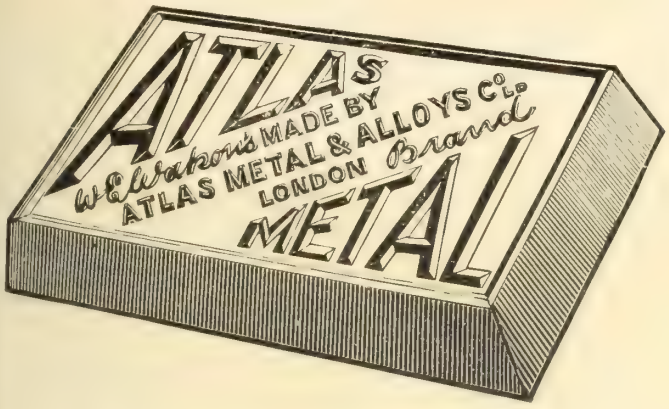
Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work, by reason of their high air efficiency, substantial design, and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)

SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines, in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.



Electric Chain Machines **Diamond Drills** **Automatic Car Dumps** **Ventilating Fans**

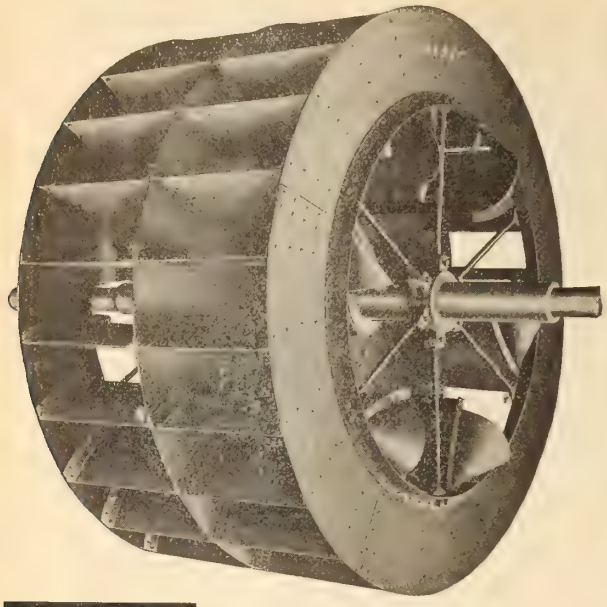
RAND AIR COMPRESSORS

EFFICIENT AND ECONOMICAL



Complicated mechanism in air compressor design is regarded as an element of weakness and it is the elimination of such non-essentials that has produced the up-to-date RAND Machine; a machine which operates with the minimum of attention and repairs.

Our Catalogs describe Rand Compressor Construction.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 500,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

R. C. DRINNEN, Superintendent.

C. C. S. LINDSEY, General Manager.

REVIEW.

Official returns indicate a pronounced improvement in industrial conditions. The demand for labor became active in April and has continued to grow. In the Northwest Provinces seeding was completed at least three weeks earlier than was possible last year. Everywhere, east and west, the weather conditions appear to give promise of good crops Orchards are flourishing, trade is being pushed on a large scale, and a general tone of optimism prevails.

Directly and indirectly this favorable state of affairs will react upon mining. Collieries will be taxed to their limit to supply regular demands. The Western coal mines, a portion of whose product is consigned to the smelters of Southeastern British Columbia, will have no easy task in keeping pace with these requirements now that smelting operations have been resumed.

The extension of the lead bounty, the resumption of dividends on Granby, the admission of zinc-sulphide ores into the United States free of duty, the establishment of a zinc smelter, are incidental, but important circumstances. Along with these, the activity of the important metalliferous mines of Southeastern British Columbia is distinctly encouraging.

Prospecting and mining were never more extensively carried on in Ontario than at present. From Wabigoon and the surrounding districts come reports of a revival of gold mining. The Sudbury region is normally active. Cobalt is shipping increasing quantities of ore. The Montreal River and Lorrain regions are being developed as rapidly as circumstances will permit, and the adjoining portions of Quebec are coming in for a fair share of attention. The iron industry of Ontario, while it is by no means dormant, is not receiving the same impetus. As an essential and basic industry it now calls for more notice from the powers that be. Graphite and asbestos mining in Quebec are flourishing.

Nova Scotia's coal trade will presumably be larger than in previous years. At Sydney and Sydney Mines, the Dominion Steel and the Nova Scotia blast furnaces are in steady operation. The pig iron output of the latter company for May exceeded that of any similar period in its history.

A cursory survey of the whole Dominion convinces the observer that healthy and constant progress is being made.

Nothing will contribute more largely towards prosperity than an unshaken belief in our high destiny as a nation. The status of no industry warrants that belief to a greater degree than that of the mining industry.

LA ROSE FLOTATION.

Comment is called for on the launching of La Rose Consolidated. For many months street rumors have been current to the effect that this syndicate or that syndicate was about to purchase the famous mine from which the new company takes its name. A singular feature connected with La Rose mine is that some dozens of promoters claim to have been within an ace of handling it. All of these gentlemen may be speaking with an honest inward conviction of what they could have done, but the fact remains that they accomplished nothing.

Meanwhile a $6,500,000 consolidation has been launched upon a rather unreceptive market. At date of writing only very light transactions have been recorded in New York and Toronto, and the stock is yet selling below par.

The times have changed. Had these properties been offered to the public a year ago there is no doubt that the stock would have been eagerly taken up. But time also has changed in respect of capitalization. Twelve months ago such a consolidation would have been organized at twice or thrice the present nominal capital.

La Rose mine is known to be rich. Its ore reserves are thought to be practically untouched. It is fairly well equipped with machinery. La Rose extension has no market value, beyond the consideration that it adjoins La Rose. It is totally undeveloped.

The University, for which a large price was originally paid, is an equipped and fairly well developed mine.

On the Violet a shaft has been sunk 150 feet and a small amount of drifting performed. Its value is unproved

The Fisher-Eplett claims and the Silver Hill group add little positive value to the company's holdings. The Princess also may be relegated to a position only slightly better than the last named properties.

Hence the future of the venture will be the future of La Rose mine, as a mine, and not as a gaudy bait. It follows that the public have a right to full information as to what they are buying. If La Rose mine is as rich as it is reported to be, there is no need of resorting to the ordinary stock-jobbers' expedient of publishing sensational advertisements and impossible news items. If there is something to hide the stock should be left severely alone. If there is nothing to hide, a mining engineer's report should at once be made public.

This is the more desirable, as it is almost unbelievable that the owners of La Rose do not intend to work their mine on its own merits for themselves. In fact this item is the fly in the ointment.

If as a close corporation La Rose has not been a success, what guarantee is there to the investing public that, diluted with unimproved property and handled by market manipulators, the mine will pay dividends?

One conclusion is inevitable. The mine or mines must be placed under the supervision of a general manager, who not only must be a mining man of ripe experience, but must be so situated as to have an absolutely free hand. Also he must be, in character and attainments, a man in whom the public has unreserved confidence. Indeed, in a sense, this official is required as the representative of the public.

Of the present directorate's ability to make a success of the new venture there is much cause to be doubtful.

LEAD BOUNTIES.

The Hon. W. S. Fielding, Minister of Finance, has given notice of a resolution extending the period under which bounties on lead will hold good. The extension provided for covers five years, from June 30th, 1908.

The Act in force since June 30th, 1903, made provision for regulating the bounties by the standard price of pig lead in London. Whenever the London price rose to £12 10s. per long ton, a gradual diminution of bounties ensued automatically. When lead sold for £16 per ton, no bounty was paid. This fixed the minimum selling price of £16 for the producer.

Under the provisions of the new bill the standard price is fixed at £14 10s., beyond which point the bounties decreases regularly. Further, the payment of bounties in any fiscal year, until June 30th, 1913, is no longer to be limited to $500,000. But the total of all sums paid under both Acts must not exceed $2,500,000.

The subject of lead bounties was discussed at the Ottawa meeting of the Canadian Mining Institute. A resolution was then passed strongly urging the Government to renew the bounty which was to have expired on June 30th next. One of the chief arguments in favor of renewal lay in the fact that although $2,500,000 had been appropriated for bounties extending over the first term of five years, 1903 to 1908, only about $700,000 of this had been actually paid out. The comparatively low price of lead at which the bounty became inoperative and the steadiness of the lead market at a figure but slightly in advance of the point at which bounties vanished, combined to discourage British Columbian producers.

It was recognized that either the production of lead must cease or some stimulant be applied. It is claimed that when lead is selling in London at £18 per long ton the British Columbian producers need no help. When the price drops below this point they are to be assisted on an increasing scale until, when the metal sells below £14 10s., they received the maximum bounty. In other words, the fixed minimum price guaranteed to Canadian producers is now £18 instead of £16 as heretofore At least this is the figure specified in the memorial submitted by the Canadian Mining Institute. Despatches received from Ottawa are not entirely clear upon this point, but we take it that it is the only reasonable interpretation.

Our Western lead miners are forced to contend against a United States import duty of 2⅛ cents per pound on pig lead and a correspondingly heavy duty on lead ores. The expense in reaching other markets is high and, until the industry has attained greater proportions and firmer roots, help is imperative.

STANDARDIZATION.

Carrying out their praiseworthy work of standardization, the sectional committees of the Institution of Mining and Metallurgy are issuing circulars, on each of which pertinent and comprehensive questions are printed. Space is left for answers and members of the Institution are requested to full in and return the forms.

Two of these forms have reached us recently. The first is that prepared by Sectional Committee "B." The letter accompanying the circular explains that Committee "B" has to do with recommending methods of reporting the results of assays and of metallurgical and other trials, of which assays form an essential part. The necessity of specifying if "fire" or "wet" methods have been used, or if the sample was assayed in an "air dried" or artificially desiccated condition, is alluded to.

Already six standard definitions have been accepted. The word "ton" is taken as representing a weight of 2,000 lb. avoirdupois (29, 166.6 oz. troy), and fractions of a ton are to be expressed in decimals, not in "hundred-weights" and "quarters." Gold and silver returns are to be written in terms of "fine gold" and "fine silver," and the word "bullion" no longer used in this connection. The return of the gold contents of ores, money value as well as weights, are to be reported. A value for the troy ounce of 85 shillings (or $20.67) is to be taken as a constant. The centigrade thermometric scale is recommended for universal use. The word "gallon" shall represent the Imperial gallon measure of 10 lb. of water. For sieving tests the I. M. M. Standard sieves shall be used. Otherwise the widths of the apertures shall be stated.

Sectional Commitee "E" was appointed to take up the standardization of mine accounts and cost sheets from the mining engineer's point of view. Definitions of capital expenditure, both before and after the producing stage has been reached, are asked for. In the same way expenditure on development and shaft sinking is the subject of set questions. Other and most important items included in the schedule of interrogations are contingent funds, depreciation, segregation of working costs, ore in reserve or in dumps, etc., etc.

It would be difficult to estimate the importance of this effort towards standardization, especially in reference to mine accounts. A clear understanding of the exact meaning of the term "capital expenditure" would be of great use both to the engineer and to the investor. This and many other terms are used loosely, often with mischievous effect. Precise definitions, arrived at by means of circulars such as those before us, will help to establish sound relations between the investor, the engineer, the accountant and the assayer.

OBSTRUCTION.

This is the summer of our discontent. What with two Provincial elections just over and done with, a Federal election imminent, and a Presidential election approaching rapidly in the small Republic to our south, the air is electric with painful recriminations and adjectival amenities.

Possibly the very tenseness of the situation has got upon our nerves. But, whatever the cause, we cannot refrain from treading upon ground that we ordinarily take the greatest pains to avoid.

In our last issue we expressed our unvarnished opinion of the attitude of part of the public press towards the mining administration of Ontario. In doing this we, in no sense, became the apologists of the present Provincial Government. To be quite frank, we have often had cause to deplore the unmeasured praise poured upon the local Ministry's unwilling heads by newspapers of their own political color. So far as the Department of Mines is concerned, neither unqualified censure nor unstinted praise is deserved, nor should either be offered by any respectable journal.

But we wish just now to refer to certain pains and penalties that the mining community is suffering, because of the political situation at Ottawa

The Geological Survey Branch of the Dominion Department of Mines begins early in each year formulating plans for the summer's work. According to press despatches, about fourteen parties were to have been sent out west this spring. The exploitation and development of Canada's mineral resources are dependent upon the works of these parties to a degree hardly realized by the public. To ensure efficiency and economy the parties, especially those whose instructions carry them far afield, must have all in readiness early in the spring. The principal outlay of the appropriation is made in the purchase of tents, canoes, supplies, and transportation. Therefore the bulk of the appropriation is needed early in the year.

It is a sad fact that the only lethal weapon in the possession of his Majesty's loyal Opposition at Ottawa is that double-bladed axe *obstruction*. By the exercise of certain prerogatives all votes of supplies can be blocked. And at present they are being blocked.

Whether this is "good" politics, "bad" politics, heroism, or original sin, we stay not to enquire. But we linger to notice that the work of the Geological Survey has suffered delay already and may be altogether hindered if the deadlock is continued.

Hence we most respectfully (but insistently) submit that the interests of the mining industry (an industry peculiarly susceptible to chills, fevers, and vapours) must not be sacrificed even for the good of a fighting Opposition.

All of which emphasizes strongly the fact that important branches of the public service, especially the two branches of the Department of Mines, should be removed entirely from the zone of political disturbance.

THE SUMMER EXCURSION.

On another page we present the provisional programme prepared by the Secretary of the Canadian Mining Institute for the visit of the British and European delegates next August. It is the wish of the committee appointed by the Council of the Institute that the programme be made final as soon as practicable. Hence members of the Institute and others interested in the event will do well to communicate with the Secretary at once if they have changes to suggest. The programme is submitted for criticism, but time is limited and preparations must be completed at the earliest possible moment.

By the courtesy of the Commissioners of the Toronto National Exhibition, a luncheon will be tendered the visitors on September 4th. To accentuate the occasion further, space has been reserved for a strong exhibit of mineral specimens, metallurgical products, and mining machinery. Intending exhibitors should write to Dr. Orr, whose office is in the City Hall, Toronto.

IS THIS A WORLD'S RECORD?

On May 14th, Nos. 2 and 9 collieries of the Dominion Coal Company, Glace Bay, N.S., recorded a coal output of 5,100 tons, from one shaft, in one day. This, we believe (subject to correction), is a world's record. We believe also that these figures will have been exceeded before we have sent this number of "The Canadian Mining Journal" to press.

Such records, unlike the high water marks of one day's production of pig iron from one stack, are authentic and indisputable. A blast furnace can be so handled as to be left with a full crucible on change of shift. The enormous daily outputs of American stacks are often obtained in this way But the amount of coal actually hoisted to the surface from one shaft can be taken as a true measure of work done.

AN APOLOGY.

Our last issue contained a tabulated account of a hammer drill trial conducted in Cobalt some weeks ago. This account was forwarded by Mr. A. A. Cole, mining engineer of the T. & N. O. Commission. It was Mr. Cole's express wish that this should be published without comment. Through an entire inadvertence a note was appended commenting upon one of the drills. Mr. Cole was naturally not responsible for this.

Our prompt apology is due Mr. Cole. Through his energy and courtesy we have been provided with much valuable information. We heartily regret that this mistake occurred.

DISCOVERY.

Dr. R. W. Raymond contributes to this issue of "The Canadian Mining Journal" an article that will be welcomed by all Canadians interested in mining.

The importance to be placed upon the discovery of valuable mineral "in situ" is the point discussed by Dr. Raymond. It will be noticed that the distinguished writer assumes a position that is constructively critical. Existing evils, he says in effect, may be much more tolerable than ill-considered change.

Dr. Raymond's utterances are always worthy of respectful attention and consideration. His long experience, his keenly analytical mind, and the unique advantages that his official position as Secretary of the American Institute of Mining Engineers affords him, contribute to lend value to his pronouncements.

No better beginning than this could be wished for a general and profitable discussion of Privincial mining laws. We shall be pleased to hear from our readers.

Editorial Notes.

The Mining Society of Nova Scotia has issued an invitation to the Canadian Mining Institute and the expected British delegates to visit Sydney in August next as the guests of the Mining Society of Nova Scotia. The invitation has been accepted. The Mining Society of Nova Scotia will take full charge of the excursion on its arrival at Sydney and arrange all the details for the entertainment of the guests. This is tantamount to a statement that the visit will be an unequivocal success.

Litigation over mining troubles brings to light the amazing ignorance of the legal fraternity as regards the commonest technicalities of the mining profession. More often than not a learned judge will listen respectfully to a harangue from a discredited "expert," and will fail to be impressed by the carefully prepared statement of a qualified mining engineer. Mining jurisprudence is a much-neglected subject in Canada. The sooner this is recognized the better. Very little study would put an intelligent lawyer in a position to discriminate between the wordy "expert" and the genuine mining man.

DISCOVERY BEFORE LOCATION.

Written for The Canadian Mining Journal by Dr. R. W. Raymond.

The law of the United States concerning the sale of mineral lands differs from that of Ontario in many respects. With us, a solid lode or placer location made on the public domain withdraws the located tract from that domain, and rests in the locator a possessory title, indefinitely continued so long as certain conditions of annual work are fulfilled, good against any subsequent claimant, and transformable, upon certain conditions and proceedings, into a fee simple, at the option of the locator or his grantee. To make the original location valid, however, it must be based upon the discovery of a mineral deposit within its boundaries. The complications and doubts introduced into the value of the title ultimately granted by the United States patent by the grant (and corresponding reservation) of "extralateral" rights must not be here considered. Apart from these, the whole purpose of the United States law appears to be to encourage the exploration and exploitation of the public mineral land, and the complete transfer to private owners, on easy terms, of the title of the United States, without reservation of royalty, or subsequent control of mining operations.

In view of this liberal policy, the requirement of a "discovery," as the basis of the possessory title, was included in the law, with the view of preventing the location and appropriation of mineral land by those who had not discovered valuable mineral deposits therein. But this provision has done little good and some harm, for the following reasons:

1. The fact and the value of the initial discovery is not authoritatively determined at the time. The fact of the location creates a legal presumption of the discovery, which must be overthrown by evidence to the contrary.

2. A subsequent discovery made by the locator before other claimants have intervened, may correct the lack of a valid discovery before location.

3. Our courts have held in some cases that signs of a mineral deposit sufficient to warrant mining exploration, though not presenting at first proofs of actual value, are sufficient basis for a location.

As I have elsewhere declared, I think that the requirement, under the circumstances of the preliminary discovery of a mineral deposit, is not only unnecessary, but harmful. So long as the possessory title depends upon annual work, upon the cessation of which the tract reverts at once to the public domain, this condition should sufficiently protect the United States against the schemes of those who would hold land without developing its value. Even if the location of land not containing known mineral deposits of value should come forward as purchasers, and ask for a patent conveying full title, I cannot see what harm would come from granting their request. The declared policy of the United States being to sell its mineral land at $5 per acre to any citizen desiring to buy it, after spending a certain sum upon a tract of a certain size, and paying the expense of surveying, advertizing, etc., I do not understand why the Government should say "I will sell you this land at this price, if you have proved it to be worth a good deal more; but if it has never been shown to have any value at all, you cannot buy it."

I could understand this policy, if the United States made any difference in the price according to the known value of the land. But that is not the case. A locator of about 20 acres can work on his location, without buying it, until he has shown it to be worth a million dollars. But that makes no difference to the government. He buys it for $100, just the same. But if it is and has always been worthless, he cannot buy it at any price! The natural result of such a policy would be to leave the public mineral domain like a blanket full of holes, the portions showing mineral value on the surface having been located and appropiated, and the rest being left on the hands of the government. That such a result has not yet become evident, is due to the extreme liberality with which the requirement of a preliminary discovery has been construed and enforced—a liberality so loose that I am inclined to think it has practically nullified the requirement, except in certain cases, where it is appealed to as a technicality, to facilitate litigation. The evils, dangers, and abuses which this provision was expected to prevent can be better prevented in other ways. Meanwhile, so long as our government desires to sell and get rid of its public mineral land, its policy should obviously be to encourage as far as possible the exploration and sale of those which are apparently worthless.

Above all, it is wisdom as well as justice to make all titles definite and indefeasable from the beginning, and not to leave them dependent upon subsequent developments or opinions. Whatever be the initial requirement, its performance should be certified and recognized at the outset, beyond any later reconsideration, except in case of alleged fraud. It is both an outrage upon individual adventurers and a curse to the mining industry of any country, that the laws should permit the uprooting of mining titles upon such vague pretexts as the nature and value of the original "discovery," long after the innocent grantees of the original locator have entered into bona fide possession and risked their money in bona fide exploration and exploitation.

How far the foregoing considerations may be pertinent to the present mining law of Ontario, I will not here undertake to inquire. According to my impression, the provision of "inspection for discovery" was introduced into that law for the purpose of preventing "blanketing"—i.e. the control of large areas by individuals or companies. This is by no means an unmitigated evil. While it may be thought necessary to appease, by disposing of mineral lands in small parcels, the popular clamor raised by prospectors and small promoters, the final result in any premanently productive mining region is sure to be the consolidation of properties into aggregates sufficiently large to warrant the investment of adequate capital for regular and long continued operations. The right to sell is part of ownership; and to grant a small tract to an individual without leaving him free to sell it is not to grant it at all. If he could sell it to a "capitalist," he wouldn't desire it for himself. And so it comes to pass everywhere that capital ultimately gets hold of mining properties big enough to be successfully worked. Whether it is worth while in the long run to make the process so difficult and so dear that capital can not afford the risk of it, is a serious question, on both sides of which much might be said. Meanwhile, I must frankly say

that I do not think the requirement of a discovery is the best way to reach the objects, even of the advocates of that provision. Yet the change of a system in one particular may involve many complications in other particulars; and, since I do not now mean to propose a new mining law for Ontario, I must not be understood as definitely advocating a specified change of that law in one feature only.

BREATHING APPARATUS FOR USE IN MINES.

By Professor Leonard Hill.

Section II. of a paper read before the British Federated Society of Mining Students:

The Fleuss-Siebe Gorman dress of to-day is the perfected form of the apparatus which Mr. Fleuss exhibited in 1880 to the Institute of Engineers of South Wales, and with which, in a form modified for use under water, he saved the Severn Tunnel from flooding. (Trans. Vol. XIII. p.p. 180 and 330.)

"On arriving at the Tunnel Works with his diving apparatus, he went down the shaft and some distance along the subway, but as he had never been underground before, and everything was strange to him, he could not penetrate as far as the door, which had been left open by the men when the spring was struck, and on returning to the surface he said he would go down again if they would allow him to make a second attempt. The diver (Lambert), however, then offered to go down in his dress and apparatus, and, after explaining to him the mode of using it, he did so. The diver had to cross over two trams which had been left on the road, remove some metals which were jammed in the door, close two sluices, and shut the door, all of which he successfully acomplished in about one hour and a half. The depth of the shaft was about 210 feet, in which there was about 39 feet of water when he descended, and he had to travel along the submerged subway from the bottom of the shaft and back again."

Subsequently to this the original Fleuss apparatus was used "for conducting some of the most dangerous of the exploration work at Seaham Colliery, after the fire which succeeded the unfortunate explosion which took place at that colliery in 1881." (S. Wales Institute of Engineers Trans XII., p. 575.)

Mr. H. H. Hedley, who made the report to the same Institute, says:

"The novelty of the apparatus and the principle on which it depended, which at first sight would seem obscure to any but a chemist or physiologist, might lead to the supposition that there would arise some difficulty in its ready use by uneducated or unskilled hands, but the result shows that these fears were groundless, and that there was no practical difficulty in its application. The men were enabled, by using the breather and Fleuss lamp, to penetrate into the workings, which were filled with gas (fire damp), to a considerable distance—in one instance upwards of 300 yards in advance of the bratticed air—and were able to report as to the state of roof, road, etc."

Mr. Hedley used the apparatus himself, and found a mouthpiece and goggles much more convenient and comfortable to wear than the mask: the mask, he says, became painful after a short time, owing to the pressure of the bands on his head.

These examples showed how the Fleuss apparatus of twenty-five years ago could be used effectively and safely, even after the briefest training.

The apparatus now exhibited has been perfected so as to satisfy the requirements established by exact physiological investigation, and to give the greatest simplicity and strength with maximum comfort and safety.

The Equipment and Speed of Dressing.—The apparatus is carried in a strong leather and canvas equipment so arranged as to distribute the weight equally and comfortably, and at the same time, to give the wearer free movement of his arms. In the latest design the whole of this equipment is in one piece, consisting of a back-piece to carry the oxygen cylinders, and a breast-piece to carry the breathing bag and gauge; the back and breast pieces are connected by shoulder straps leaving a hole for the head. This equipment rests in readiness on a saddle, and the wearer catching it up can put it on in a moment. The equipment allows the wearer to be stripped to the waist, and covering little of the body permits free perspiration. Masks and tunics must not be used in hot moist atmospheres of mines, if heat-stroke is to be prevented. The inlet and outlet orifices of the breathing bag are closed by rubber corks. These can be withdrawn in another moment, and the flexible tubes leading from the mouthpiece inserted, together with the oxygen supply tube. The mouthpiece is placed in the mouth, the clip on the nose, and goggles on the eyes, and the man is ready. The whole performance can easily be done by the wearer himself in less than one minute. The oxygen bottles, of strong British make (in accordance with the recommendation of the Royal Commission), are carried in the small of the back, and are so slung from the shoulders as to give the minimum sense of weight.

Avoidance of Projections.—The back behind the shoulders is quite free, enabling a man to get along in a low mine road without the least danger of displacing unstable timber or rock. The wearer can crawl through a space measuring seventeen inches wide by seventeen inches high. The wearer knows that if his head and shoulders can pass in the crawling posture, the rest of his body, including the oxygen cylinders, can follow safely. The figure makes this clear.

It is most essential that the danger of the wearer displacing half fallen debris by projecting apparatus should be avoided, and it is equally essential that he should be able to creep through the minimum of space. Nevertheless in all other forms of apparatus the most bulky parts are placed on the back of the shoulders, and the wearer can have no knowledge of the proximity of these to the dangerous unstable structures which may surround him when exploring a seam after an explosion. The Fleuss-Siebe Gorman apparatus is arranged so that the head and shoulders can act like the vibraeula of a cat's whiskers, which tell it whether it can pass through a hole or not.

The apparatus is made with the fewest possible connections, and these are all controlled by one spanner. Thus any man can learn to put it together in a few

minutes, and there is no danger of any of the parts being misplaced or broken.

Valves of Oxygen Supply.—The oxygen cylinders are controlled by valves which do not allow the cylinders to leak when not in use. A reducing valve has been added which delivers approximately two litres of oxygen per minutes at all pressures. This means a slightly wasteful us of oxygen when the wearer is not working, but waste is deliberately chosen in preference to the risk of deficient oxygen. The Royal Commission on Mines have reported strongly in this sense. A relief valve is placed on the breathing bag, so that the wearer can let out the excess in case the bag becomes overfilled and expiration impeded. In spite of the necessary waste, the oxygen cylinders contain a supply sufficient to last two hours. A bye-pass fitted with an emergency valve is added, so that the wearer can fill the bag at once on first putting on the dress, or obtain an immediate supply if at any time his bag is accidentally compressed (and the gas driven out of it round the mouthpiece), or if the reducing valve fails to act.

An experienced wearer could safely set the reducing valve at one litre per minute and obtain a larger supply when needed during great exertion by means of the emergency tap. By this means he could extend the available time of the oxygen supply to about three hours. For general use it is wiser to diminish the available time in order to gain absolute security from deoxygenated air. Analysis taken when the Fluess-Siebe Gorman apparatus is in use show there is 50 to 80 per cent. of oxygen in the breathing bag.

Capacity of Breathing Bag.—The breathing bag is of ample capacity to yield a sufficient volume of air during the deep respirations of hard labor. It also acts as an efficiency elastic cushion to render the respiration easy and comfortable.

The Absorption of Carbonic Acid.—The caustic soda is placed within the breathing bag in the form of sticks. The bag can be opened and the sticks dropped in with the greatest ease and quickness, and the vulcanized india-rubber bag can be washed clean of the used soda under a water tap with equal convenience. There are exhaling and inhaling divisions in the bag to ensure the passage of the expired air through the soda. With each movement of the wearer the breathing bag is jolted and the carbonised surface is rubbed off the soda. A fresh surface is thus being constantly exposed for the absorption of carbonic acid gas. In other apparatus the caustic soda chambers are made of metal and are carried on the back of the shoulders, increasing the bulk, weight, and awkwardness of the apparatus.

Analyses show that the carbonic acid gas in the breathing bag keeps under 0.5 per cent. in conditions of hard labor when pure caustic soda (free from water) is used. The percentage may temporarily rise to 2 per cent. if hard work is done while the caustic soda is still cold, that is, before active chemical action has be-

Fig. 1

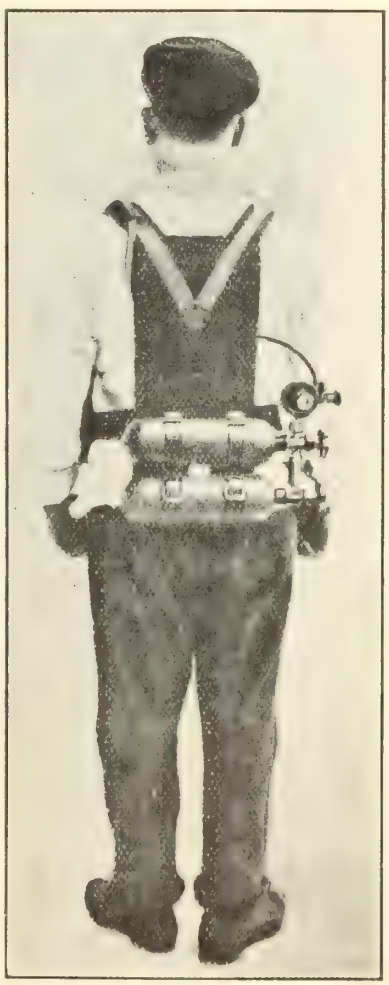

Fig. 2

The Fluess-Siebe Gorman Dress placed ready for use by the Wearer.

gun (or even 2.32 per cent. as on climbing stairs in one of the experiments of the Royal Commission). If the wearer rests or shakes the bag, the percentage immediately drops again to below 1 per cent. There is no risk or noteworthy discomfort produced by breathing a percentage of CO_2 up to 3 per cent., and the advantage of carrying the caustic acid in this simple manner outweighs any risk of slight and temporary increase in depth of respiration; this is the only result of breathing from 2 to 2.5 per cent. of CO_2. To overweight the apparatus or render it clumsy in order to obtain very low percentages of CO_2 is, in regard to breathing apparatus, a most mistaken policy.

The efficiency of the apparatus is shown by one of the wearers having performed 345,000 foot-pounds of work, on a single charge, in two hours.

The Gauge Visible to Wearer.—The pressure gauge is attached by means of a strong flexible tube to the front of the breathing bag, so that the wearer can tell at any moment the oxygen supply he has left, and beat a retreat at the right moment. This is an absolutely essential improvement, one on which the life of the wearer depends, but one that exists in no other apparatus.

The Mouthpiece.—The mouthpiece allows the wearer free movement of his head, being connected to the breathing bag by strong flexible corrugated tubes. The inhaling and exhaling valves in the latest pattern are of mica, and being of the simplest design, do not stick or get out of order.

The dead space between mouth and inlet to bag is not greater than from 150 to 160 c.c.

The mouthpiece is attached by a small rubber band which fits comfortably round the outside of the mouth, and buckles behind the head. The band prevents the mouthpiece from being jerked out.

The rubber parts of the mouthpiece which come in contact with the gums are soft and comfortable. The mouthpiece can easily be slipped out and the orifice closed by the thumb, thus enabling the wearer to say a few words of direction, or drink from a flask before replacing it in the mouth. This is a point of no little importance.

The nose clip is made comfortably to fit any nose.

Fig. 3

Fig. 4

Figs. 3 and 4.—Illustrating the Dress in use in the Exploration of Obstructed Mine Passages containing Irrespirable Gases

and cannot slip off. Mica goggles are supplied to protect the eyes, (in place of mouthpiece, nose clip and goggles, a half-mask can be worn if preferred), during work in smoke.

The report of the Royal Commission of Mines summarizes the data obtained as to the four points, (1) removal of carbonic acid, (2) supply of oxygen, (3) air tightness, (4) comfort and convenience, and gives the mark "Good" in all four to two forms of apparatus only, the Fleuss-Siebe Gorman, and the "Weg." The report, however, points out that in the case of the "Weg" dress, there is danger in the method by which the oxygen supply is delivered. This is shown by the analyses given on page 39, wherein the oxygen in the breathing bag is shown to have fallen, after exertion, below the danger limit, viz., to 10.6 per cent. The report says that this danger can be obviated "if the subject draws on the supply in the cylinders in slight excess of his actual requirements, and so washes out the apparatus during the whole period of use, and wastes some of the oxygen, and the conclusion reached is that the constant arrangement of an excess supply, as in the Fleuss-Sibe Gorman, is preferable. Such a supply relieves the strain of attention on the part of the wearer, and of anxiety concerning it, and sets him free to attend to his work. The Weg apparatus is "made only with a mask, and the construction of this, and its connections with the purifier and breathing bag by means of rigid tubes, necessitates the head-piece of each apparatus being made to fit only one individual." (Report of Commission.)

This seems to be a distinct disadvantage. The Fleuss-Siebe Gorman dress can be made to fit any man by adjusting the length of the straps. Its weight, fully charged, is only thirty pounds (as against the Draeger, thirty-nine pounds, "Weg," thirty-eight pounds), or less than the equipment of a soldier in full marching order. The oxygen capacity of the "Weg" apparatus is only 5.4 cubic feet. That of the Fleuss-Siebe Gorman 9 cubic feet.

It can be claimed, therefore, with some justice, that the Fleuss-Siebe Gorman apparatus is the most convenient, safest, simplest, lightest, and strongest on the market.

[Note.—Professor Hill has kindly promised to give a practical demonstration of Rescue Appliances at the Spring Meeting of the Society, and so add to the interest of this paper.]

INVESTIGATIONS RELATING TO GOLD AND SILVER BY THE UNITED STATES GEOLOGICAL SURVEY IN 1907.

(Abstract of advance chapter from Bulletin No. 340)

The Production of Silver.

Previous to 1859, the production of silver in the United States reached a maximum of only 38,500 fine ounces per annum. In 1859 the output rose to 116,000 ounces. In 1861 the figure attained was 1,546,900 fine ounces, and thereafter the increase was rapid, owing to the new discoveries in Nevada and Colorado. For 1876 the figures had almost reached 30,000,000 ounces. From 1876 to 1892 was the time of bonanzaz in Nevada, Arizona, New Mexico and Montana, and in the latter year the maximum of 63,500,000 fine ounces was recorded.

It was during this period that, owing to the production of silver as a by-product from lead and copper smelting, a serious decline in price commenced. As far back as 1833 a steady price of about $1.30 had been maintained. But from 1875 to 1892 the decline was continuous, and in the latter year the price fell to 87 cents per ounce. The failure of the old silver milling camps where pan-amalgamation was practised was inevitable.. However, silver as a by-product continued to be put upon the market and in 1894 a production of 49,500,000 fine ounces was attained. The next year the production rose to nearly 56,000,000 ounces. Since that time the production has remained approximately constant.

Geological Conditions.

Native silver is almost invariably due to oxidizing surface processes acting on primary argentiferous sulphides. One class of silver bearing veins is contained in granitic rocks or is accompanied by consolidated porphyries at depth. The normal gangue of these veins is white massive quartz through which the sulphides are sparsely disseminated. Such veins are apt to be rich near the surface, where secondary sulphides and sulphantimonites have formed, but generally they are disappointing below the water level, where the primary ore is reached. Others of similar type contain more abundant sulphides, among which galena generally predominates and may be successfully worked by concentration even below the surface zone of enrichment.

Another class of silver veins cut through volcanic flows which have consolidated at or near the surface. It can be proved that many of these veins were formed at very moderate depths. The gangue is prevailingly quartzose, but usually very fine grained, chalcedonic, and drusy, and in many places it contains adularia. The quartz is characterized by primary argentite accompanied by very small amounts of lead, zinc, and copper sulphides. In dry climates oxidation and the secondary deposites of sulphantimonites have enriched the upper parts to an extraordinary degree.

A third class of silver deposits are found in limestones and here generally in connection with intrusive rocks—granite, diorite, monzonite, or other porphyries. Almost without exception these ores contain lead, and usually copper and zinc. In their primary forms the value of the base metals generally exceeds that of the silver. Both quartz and calcite appear in the gangue. Secondary silver sulphides or sulphantimonites are less common in these ores near the surface, but native, and especially horn silver form abundantly. Mechanical enrichment by the solution of the limestone aids the ordinary concentration by oxidation, and thus the upper parts of many such deposits are extremely rich. Oxidized iron and manganese ores, almost free from lead but containing silver, are among the end products of the oxidation of these deposits.

Very likely it will be found that the three classes of ores mentioned are simply diverse products of the same vein-forming action; their characteristics being dependent on the depth below the surface and varying physical conditions, or on the caracter of the rock affected.

Classification of Ores.

The gradations between ores that may be selected as types make classification difficult. Nevertheless it is possible to arrange them in certain groups, on a metallurgical basis. Hence the silver product is divided ac-

cording to its derivation from placers, dry or siliceous ores, copper ores, lead ores, zinc ores, and mixed ores. Ores containing 2½ per cent. or more of copper are designated as copper ores. Those containing over 4½ per cent. are called lead ores. The dry or siliceous ores contain either very small amounts of copper, lead, or zinc, or none at all.

Silver produced in the United States in 1906 was divided thus:

Sources of silver produced in the United States, 1906.

	Fine Ounces
Placers	171,058
Dry or siliceous ores	16,792,799
Copper ores	15,880,870
Lead ores	15,328,653
Zinc ores	98,423
Mixed sulphide ores	9,090,650
Total	57,362,453

About 30 per cent. of the total silver production is derived from dry or siliceous ore and these ores constitute about 39 per cent. of the total tonnage of deep mines.

Siliceous Silver Ores.

Dry or siliceous silver ores may be defined as those in which the value of the silver is equal to or greater than that of gold, and in which copper and lead are below 2½ per cent. and 4½ per cent. respectively. In other words, on the basis of 62 cents per ounce the ore contains at least 100 ounces of silver to 3 ounces of gold. In 1906 the United States produced only about 700,000 tons of dry or siliceous silver ore, containing approximately 12,000,000 ounces of silver, $2,000,000 of gold, about 7,000,000 pounds of lead, and 80,000 pounds of copper. The silver ores clearly contain very little copper and three-fourths of this comes from Colorado. The silver ore is derived from 12 states, being produced at 219 mines in 103 mining districts. The average content is about 19 ounces of silver and $1.85 in gold per ton.

The silver-lead-copper ores yield silver to the amount of 3,078,592 ounces. The ores average 8 ounces of silver, $1.30 in gold, and 22 pounds of lead per ton. Their sources may be classified roughly thus:

	Ounces
1. Replacement deposits in limestone.	1,305,000
2. Fissure veins, connected with intrusive rocks (not always to be separated strictly from No. 1.)	712,000
3. Fissure veins in Tertiary volcanic flows	900,000
Total	2,917,000

The silver-gold ores from which 7,584,630 ounces of silver and $1,629,975 worth of gold are derived, average 28 ounces of silver and $6 in gold. Their total tonnage is 270,000 short tons. They are mined in 8 states and constitute the output of 50 mines in 22 mining districts. The whole production of Arizona in this class is derived from fissure veins in volcanic flows, principally rhyolite or dacite. Briefly, the ores of this class appear to be eminently characteristic of veins in Tertiary volcanic flows.

The third class of the dry or siliceous silver ores may be called the pure silver ores. They consist of those which contain no reported lead or copper, and in which the proportion of gold to silver is very small—less than 0.5 ounce of gold to 100 ounces of silver. Only about 1,500,000 ounces, or one-fortieth of the total production, are derived from these ores. They average only 15 ounces in silver and 25 cents in gold. Their principal sources are:

	Ounces
Replacement ores in limestone	574,000
Fissure veins in other rocks connected with intrusions	314,000
Fissure veins in volcanic Tertiary flows	466,000
Doubtful	149,000
Total	1,503,000

A large part of these ores consists of oxidized surface ores. Some of them are oxidized iron ores from the upper part of the deposits and really mined as flux.

The total production of silver in 1906 was 57,362,455 fine ounces. Of this, 40,398,596 fine ounces were recovered from lead, copper, or zinc ores, and 16,792,799 fine ounces from dry or siliceous ores.

Analysis of the distribution of production between the various classes of ores, brings out the well known affinity of silver for lead and emphasizes the slight degree in which copper and zinc are associated with silver ores properly so called. The selective action of limestone in the precipitation of silver, lead compounds is also emphasized.

SUMMER'S WORK OF THE GEOLOGICAL SURVEY IN THE WEST.

So far as can be learned at date of writing the following parties will be sent out by the Geological Survey to work in the districts mentioned:

Mr. D. D. Cairns will delimit the coal bearing rocks of White Horse coal area.

Mr. R. Graham will make a geological study of the Pacific coast and inlets from Kingscome Inlet northward. This will be a continuation of the work of last year.

Mr. R. G. McConnell will examine the geological features of Texada Island with special reference to ore deposits.

Mr. J. Keele, who was engaged last season in exploring the Continental Divide, near the head of Pelly river, and wintered there, will this season explore the Mackenzie slope of this district.

Mr. W. W. Leach will continue his exploratory work in the Bulkley valley.

Mr. John Macoun will investigate the fungi that cause the rapid decay of mine timbers in British Columbia. Assisted by Mr. Spreadborough, Mr. Macoun is also making a collection for the new museum to illustrate the flora and fauna of Vancouver Island.

Mr. V. Stefansson has been sent out on a joint expedition under the auspices of the Museum of Natural History, New York, and the Geological Survey, to the region about Coronation Gulf in the Arctic. The geography and mineral resources of the region will be examined. The condition of life among the Esquimo, who have not come into contact with whites, will be reported upon.

Mr. Owen O'Sullivan has left for Hudson's Bay to complete the instrumental survey of the coast.

Mr. A. W. G. Wilson has gone into the Nipigon region to complete the work for a report to accompany a map now being prepared.

STANDARDIZATION.

The Institution of Mining and Metallurgy.

[Editor's Note.—The invaluable work undertaken by the Institution of Mining and Metallurgy in the direction of standardizing the terminology of mining and metallurgy has an especial significance for Canadians. Mining has increased vastly in importance as a Canadian industry within the last decade. It is undeniably desirable that Canadian mining men should be familiar with and should conform to the best usages. With this in view we invite answers to these questions.]

Sectional Committee "B."—Bullion and Assay Values.

Your opinion is requested on the following matters:

(1) Do you approve that, wherever possible, assay values of gold and silver ores and products shall be reported in ounces and decimals, or pennyweights and decimals, rather than in ounces, pennyweights and grains?

Note—For ores and products where the use of pennyweights rather than ounces would not be unduly cumbersome, it is suggested that the former be always used.

(2) Do you approve that assay values of alluvials shall be reported in grains and decimals of a grain of "fine" gold, or in pence at 2d per grain of "fine" gold) or cents per cubic yard or per ton? If reported per ton, should one cubic yard of ordinary damp alluvial, excluding boulders, be taken as equivalent to 3,000 lb.? If not, what do you recommend?

Note.—The value of 2d. per grain is suggested as convenient and sufficiently accurate. At 85s. per ounces, the value would be 2.125d. per grain. The figure of 3,000 lb. (1½ short tons) is commonly used and is suggested as a convenient factor.

(3) Do you approve that in cases where money values are given for assays of silver, copper, tin and other metals whose value fluctuates, the market price of a stated quality or brand of the metal, as taken for calculating such money value, shall be given, together with the assay value in ounces, etc., per ton, or in per cent. or other concrete quantity?

(4) Do you approve that in reporting assay values of cyanide or other solutions,

(a) Results shall be reported in ounces or pennyweights, etc., in a stated volume of such solutions?

Or do you prefer

(b) The use of the ton of 2,000 lb. instead of volume?

(5) Do you approve that in reporting assays of silver and gold products and ores, the assayer shall state on his certificate whether the slags have been "cleaned" and allowance made for cupel absorptions?

(6) Do you approve that all assay reports shall state the exact condition of the sample as to dryness, when assayed?

Sectional Committee "E."—Mine Accounts and Cost Sheets.

(1) Do you think that it is practicable to unify and state precise definitions of some or all of the many terms now used in mining accounts vaguely and with varying meanings, so that, for instance, "Cost of Ore Extraction" should mean the same thing and cover the same scope all the world over?

(2) Will you give as many instances as possible of material variations or differences in practice which in your opinion could or should be standardized?

(3) State your definition of Expenditure which can properly be termed Capital Expenditure:

(a) Before reaching the producing stage.

(b) After reaching the producing stage.

(4) Can you formulate a suitable rule to apply to the classification of expenditure, as to whether such should be charged direct—

(a) To Capital Account?

(b) To Working Costs? or

(c) To a Temporary Account (sometimes called a "Suspense" Account)?

(5) How would you deal with expenditure on development and shaft-sinking?

(a) In a mine in its initial stages of development.

(b) In a mine which has reached the producing stage.

(6) Would you differentiate between expenditure on the work of developing known ore bodies or deposits, as distinguished from work of a purely exploratory or prospecting character?

(7) Do you consider that estimates of the value (or cost) of ore in reserve or on dumps, or of the value of intermediate products or bullion on hand be taken credit for partly or wholly in accounts?

(8) Do you consider that forms for periodical mine reports, and statements of accounts, can be standardized and brought into comparative uniformity? If so, will you kindly submit examples?

(9) What terms would you use in preparing segregation of cost sheets and what would you include under each term? e.g.

(a) Cost of mine development?

(b) Cost of mining or stoping or ore extraction or any other similar expression. Should this term include cost of timbering, putting ore broken in skips, loading into cars, trucks, bins, or skips, cost of hoisting to surface, and of handling and delivery to mill or dump?

(c) Cost of reduction, milling, cyaniding, smelting, etc.?

(d) Cost of general charges and administration expenses. Should these be given under separate headings or should a proportion be allocated to each department?

(e) Cost of head office charges. Should these be included in working costs, and if so, should they be apportioned over other accounts or not?

(10) What would you include under Section (c) last mentioned? e.g., would you include the following items:

Cost of delivery from main ore bins?
Cost of coarse crushing in stonebreaker?
Cost of further crushing in stamp rolls, etc.?
Cost of roasting?
Cost of amalgamating?
Cost of grinding?
Cost of cyaniding and treating sands?
Cost of cyaniding and treating slimes?
Cost of disposal of waste products?
Cost of disposal of waste products?
Cost of smelting and refining bullion?
Cost of realization of bullion?

(11) How far would you segregate the items included under (9) and (10)?

(12) Do you approve of—

(a) Charging each department with its quota of power used? And if so

(b) On what basis or system would you allocate it to the various accounts?

(13) Would you make any allowance for depreciation? And if so,

(a) How would you charge it in accounts?

(b) What average percentage would you allow on buildings, plant, and various kinds of machinery?

(14) would—

(a) Provide for the redemption of shaft sinking and mine development in working costs? And if so,

(b) On what basis would you calculate it?

(15) Would you—

(a) Charge repairs and maintenance in your cost sheets to the various departments to which they apply? Or

(b) Treat them as one item of cost?

(16) Would you set aside as a reserve fund to meet any of the contingencies to which mines are liable—

(a) A fixed proportion? Or

(b) A proportion of the annual profits? Or would you prefer to

(c) Write down the assets on which no depreciation is allowed?

(17) How should depreciation on stores be provided for, and to what account should it be charged?

(18) On what basis would you calculate yield, working costs and profits?

(a) Per ton mined?

(b) Per ton milled?

(c) Per ton treated?

THE USE OF PORTABLE AIR COMPRESSORS.

By Frank C. Perkins.

Compressed air is utilized very largely not only for drilling and in tunnel construction, but also for bridge building and other structural work where the pneumatic hammer and other air tools are utilized to special advantage.

It is often desirable to provide a portable air compressor for operating these tools and these devices are

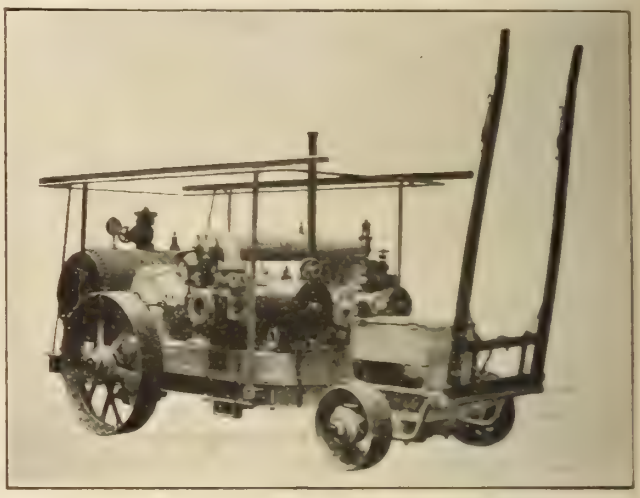

Fig. 1

now constructed not only driven by steam and gasolene, but also by electric motors to great advantage.

The accompanying illustration, Fig. 1, shows a portable steam driven set of Scotch design and construction as utilized at His Majesty's Portsmouth Dock Yard. This two stage compressor and receiver constructed at Glasgow has a capacity of 200 cubic feet. It will be noted that it is of the horizontal type with water cir-

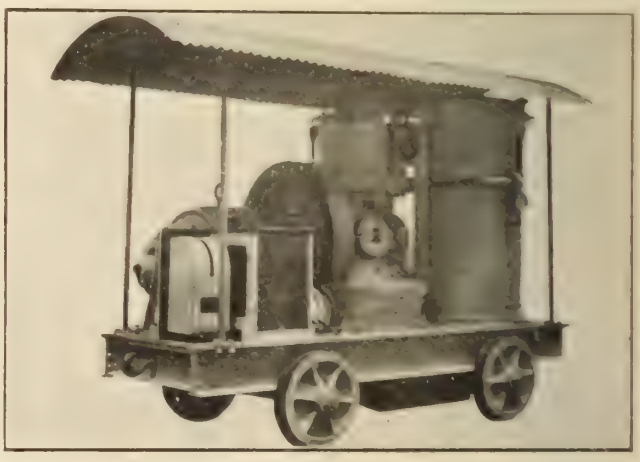

Fig. 2

culating pump mounted on a truck with wheels for road service, and is easily arranged as a stationary plant by dismantling the wheels if it is to be used for a long time at any given point.

Electrically operated compressors of the portable type are largely used in ship yards where current is available, as at the plant of the Fairfield Ship building and Engine Company Limited, at Glasgow.

The accompanying illustration, Fig. 2, shows an electric portable compressor plant of 200 cubic feet capa-

city utilized at this Scotch ship yard. It is of the vertical, two stage type, with fly wheel of large dimensions geared to the electric motor, the controller and air receiver with water circulating pump and water tank being mounted on a truck fitted with wheels for industrial railway service.

Where compressed air is used in mining and portable electric motor driven compressors are employed, it is frequently necessary that they shall be of low con-

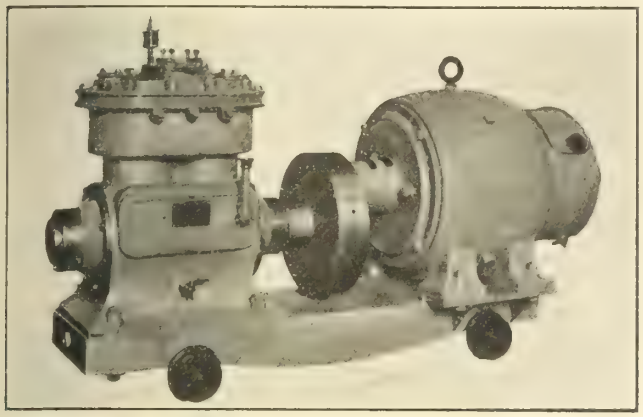

FIG. 3.

struction, as many times they are required for use in situations where the head room is scarce, and such a portable electric air compressor equipment may be seen in the accompanying illustration, Fig.3. This consists of a double cylinder, vertical compressor having a capacity of 200 cubic feet, geared to an electric motor of the enclosed type and mounted on a low truck with wheels of small diameter designed for use on the narrow gauge track used in mines.

THE GOLD ALLUVIALS OF THE RIVER DRAU IN HUNGARY.

By A. von Gernet, Member.

Paper read before the Institution of Mining and Metallurgy, April, 1908.

Gold has been produced by native diggers on the banks of the river Drau for several hundreds of years, and at the present time there are some 200 men earning their living at this work, which is being performed by most primitive methods, with an average yield of from 2 shillings to 3 shillings per day per man. Recently, a firm in Vienna obtained the rights to exploit the gold bearing gravel for a distance of 25 miles between Zakany and Visvar, and the author, who was engaged to study the proposition for the firm during the summer of 1907, obtained information which he thinks of sufficient interest to be placed before the Institution.

The river is shallow, wide and rapid, and consists of several channels having a maximum depth of 10 feet, forming a number of islands. The surrounding country to a width of from one to two miles, as well as the islands and the river bed, are formed of gravel, and at certain seasons, after heavy rains and the melting of the snow on the uplands, are covered by from 3 to 5 feet of water. At such times the stream runs at a speed of about 4 feet per second, and moves the gravel banks rapidly from one place to another, thereby changing the aspect of the river by the formation of new islands and channels. The gravel generally is 25 feet deep and rests on a clay formation.

Gold occurs in small grains, the richest places being without exception those exposed to the strongest current and composed of coarse gravel. The top layer of 6 inches frequently carries a value of from1 shilling to 1 shilling 6 pence per ton, the value diminishing in depth until at 2 or 3 feet down it is only 1 or 2 pence per ton. It is of interest to note that rich places, after being worked out, become enriched again at the next time of flood, which might last for a week or two only, and will then sometimes contain as much value as originally. Holes were sunk from 10 to 12 feet deep by means of a hand-operated dredging apparatus, and fairly uniform results averaging 1 to two pence per ton were ascertained. The same values were found when dredging in the bottom of the river bed itself.

Method of Determining Values.—It was necessary to ascertain whether panning small samples and counting colors could be relied on as a sufficiently accurate method of determining values. For this purpose a sluice-box with riffles, matting and expanded metal, capable of treating 40 tons of gravel per day, was established and kept going in various places, and simultaneously samples of the same gravel (20 pound each) were panned and the number of resulting colors were counted. The actual gold production of every lot treated was compared with the panning results.

Table of Results.

Gravel treated. Tons.	Gold produced. Dwt.*	Value per ton. d.	No. of colors per sam.	Ratio of colors per sample to pence per ton.
80	4.5	2.3	15	1 :0.153d. per ton.
100	1.66	0.7	4	1 :0.175d. per ton.
40	1.4	1.4	9	1 :0.155d. per ton.
68	8.0	5.4	34	1 :0.160d. per ton.
37	6.3	7.2	33	1 :0.215d. per ton.
68	10.0	6.2	39	1 :0.160d. per ton.
593	90.6	6.5	49	1 :0.130d. per ton.
90	5.0	2.4	20	1 :0.115d. per ton.
97	14.0	6.2	27	1 :0.222d. per ton.
98	10.0	4.3	41	1 :0.105d. per ton.
46	3.6	3.4	24	1 :0.140d. per ton.

*Bullion, 1 dwt. = 42d.

The points of interest on which the author desires to lay stress are:—

1. The rapid local enrichment of the gravel produced by natural concentration.

2. The uniformity and reliability of results obtained by panning and counting colors.

It stands to reason that the ratio between value per ton and colors per sample will represent different figures on different alluvial fields.

BENDING OF THE LAND BY STORMS.

The tilting of the ground in storms has been studied by Prof. Omori, of Japan. In October, 1904, a cyclone, the centre of which passed over the sea to the east, tilted the ground at Tokio 3½ seconds toward the area of low pressure; and, in January, 1906, a cyclone centre passing northeastward over the land near Tokio

gave a tilting first to the east and then to the westward as the low pressure moved onward, the total change of inclination being 2.87 seconds. The ground rose under low pressure while in the former case it sank—a difference explained by the fact that the rise of sea-level commonly more than compensates for lowered air pressure, so that the pressure on the sea bottom is actually greatest with low barometer.

THE SPRINGHILL BOARD OF CONCILIATION.

Failure to reach a unanimous conclusion marked the deliberations of the second Springhill Board of Conciliation.

The dispute between the Cumberland Railway and Coal Company, Limited, and certain of its employees was resolved into four separate claims advanced by Mechanics Lodge, No. 23, P. W. A.. The Board was composed of Judge Wallace, chairman; the Hon. J. N. Armstrong; and Mr. R. B. Murray, the last named was the men's representative. Judge Wallace and the Hon. Mr. Armstrong found in favor of the Company on all four counts. Mr. Murray found in favor of the men on all but one claim.

Both the majority and the minority reports are temperate in tone and the conclusions reached are carefully substantiated. However, Mr. Murray's dissenting report would have lost nothing if the last paragraph (which is not reproduced here) had been excised.

Beginning on May 13, when the first session of the Board was held in Springhill, sittings were continued throughout and the subsequent day. Deliberations were resumed in Halifax on May 18. The reports were made public on May 27th.

The following are the findings of the majority:

There are four classes of cases, "A," "B," "C," and "D," in dispute between Mechanics Lodge No. 23, P. W. A., and the Cumberland Railway and Coal Company, Limited.

Claim "A" is in respect to an advance of wages for repair work. There are two classes of men in the Mechanical branch, working on repairs, viz.,—those who labor underground, and those whose work is performed on the surface, the present rate of wage for the former class being 15 cents per hour, plus 22 per cent., and the rate for the latter class being $1.20, plus 22 per cent. per day. The wage now asked for on behalf of this class of underground and surface work is a flat rate of $1.85 per day of 8 hours for underground men, and 10 hours for surface men.

Undoubtedly the work in question is disagreeable and trying.

It is urged by the applicants, as a justification for the increase desired, that this class of work commands a higher rate of pay in some other collieries, and as proof of this contention the schedule of rates applicable to the Dominion Coal Company's employees was put in evidence. In reply, the Mechanical Superintendent of the Cumberland Railway and Coal Company testified that this class of men were paid at a higher rate at Springhill for the same number of hours, than the employees of the Dominion Coal Company. The tabulated statement marked in the written answer of the Company was also verified by the Assistant to the General Manager.

The applicants for an increased rate of pay seemingly regard this question of the rate of pay prevailing in other similar employment within the Province of Nova Scotia under similar conditions as affording a fair test to enable the Board to determine what would constitute a fair wage. Applying that test, which is generally a fair one, to the issue before the Board, and examining the whole of the evidence upon that question, the Board finds that the applicants in this class are paid at least as high a rate for the number of hours as men of a similar class employed by the Dominion Coal Company.

The Board finds that the applicants in this class have not established their claim to the desired increase.

Claim "B" is on behalf of the fan-men at No. 3 mine. An objection was raised by the Company in regard to this claim, and also to the two following claims, that as the persons affected were less than ten in number, the Act did not apply. The chairman ruled against this objection.

The present rate of wage for the fanmen per day of 12 hours is $1.20, plus 22 per cent. They ask for a flat rate of $2.00 per day of 12 hours. The Board finds that the work which they have to perform is work generally given to old or infirm employees. One of the claimants has been sick for two years and could not perform any other work, and therefore applied for this work. The other claimant had a crippled leg and he requested a similar job. It was asserted on behalf of these men, that workmen doing similar work for the Dominion Coal Company get a better rate of pay, but the Board finds that the employees doing this work at the works of the Dominion Coal Company have also the responsibility for the air compressors and that their work is substantially different.

The Board therefore unanimously rejects this claim.

Claim "C" relates to Charles Ronney. It appeared that he is in the same class and is paid at the same rate as ten others. They are not skilled workmen, but might be described as handy men. While there may be only a slight difference between this claimant and some of the men in the class just above him, the Board finds that the applicant in this case has not established his claim for the increased wage.

Claim "D" relates to the cases of Wilson Demmings, car inspector. His wage is $1.30 plus 22 per cent. per day. Applicants ask on his behalf a flat rate of $2.00 per day, claiming that is the rate which such class of work commands elsewhere. This employee has now the benefit of an assistant at his work, and the duties of Mr. Demmings have not increased since the increase of pay given him. It was amply shown by evidence to the satisfaction of the Board that Mr. Demmings is a painstaking, industrious, and capable employee, but the Board cannot find that he has established his claim to the increased rate asked for by him.

The Board deems it proper to add to its findings this statement,—that the declaration in the "ultimatum" issued by the general manager of the Company last October, when the men returned to work, "that there cannot be any increase in wages in the district covered by the award now or later," would not in any way have interferred with a finding in favor of any of the

applicants herein if the evidence submitted to the Board justified suc ha finding.

The minority report, which it was decided to forward to the Department, read in part thus:

In the application for this reference there were four cases set out as being in dispute between the Lodge and the Company, these cases were designated in the application as follows:

First case.—Is in respect to an advance on wages for repair work.

Second case.—Is in respect to an advance on wages for No. 3 fanmen.

Third case.—Is in respect to an advance on wages for Charles Ronney, carpenter.

Fourth case.—Is in respect to an advance on wages for Wilson Demmings, car inspector.

Although the foregoing cases were not taken up by the Board in the order named, it is the intention of the writer to discuss and report on them in successive following, therefore the "repairs rate" shall be the first under consideration.

The evidence disclosed that in this employ there are at least two classes of repair work in connection with the mechanical branch, repairs to steam pipes and machinery underground and repairs to pipes and machinery overground, including of boilers. In the underground section, there seems to be about ten men affected, and in the overground one man only, Andrew McCarron claimed redress at the hands of the Board. For the underground men the witnesses George McLeod and John Campbell gave evidence which seemed conclusive, that their work was performed frequently in high temperatures, sometimes at 116 degrees, their hours were erratic, being subject to a call at any time during the night when their day work is over, and in addition to this, to use their own language "we are frequently employed on Sundays." The present rate of pay for these men is 15 cents per hour plus 22 per cent., their contention being that this rate is altogether inadequate for the class of labor they are called upon to perform. In view of their receiving no excess pay for their Sunday work or extra calls, as it appears is customary in other places in similar industries and on work where Sunday labor is necessary, and in view likewise of their having to work mostly under conditions and at a temperature which they claim are hazardous and must of necessity be prejudicial to health, the claim the Lodge is making in their behalf of 39 cents per day of eight hours, extra, surely cannot be considered an unreasonable one. The Company through Mr. Muirhead, contends, that these men are sufficiently paid already. This is natural and usually the plea put forward in such cases by employers, but it does not lessen the fact of the soundness of the men's claim notwithstanding. To emphasize the reasonableness of the Lodge's contention, they put in evidence a telegram from the general manager of the Company wherein an express promise was made, that under certain conditions, this matter of repair rates would be adjusted to the satisfaction of the men interested. The Company now repudiate that telegram, or as Mr. Stewart puts it for them "the whole thing is now off."

So convinced am I that the Lodge has made its claims and contentions good with respect to this underground repair work I have no hesitation whatever in recommending that men at this class of work should be paid a flat rate of $1.85 per day of eight hours. My conviction is, taking all the circumstances into consideration, any jury in the land should award them at least this amount.

With respect to the other class of repair work, with which Andrew McCarron alone is interested, this man swears he is at present and has been for the past sixteen months employed in the class of labor known as overground repair work and tending engines and boilers at the machine shop and No. 1 mine, his duties also consist in cleaning boilers at Nos. 2, 3 and Aberdeen mines. His present rate of wage is $1.46 per day and in the Lodge's application a request was made on his behalf for $1.85 per day. His evidence shows that when he is occasionaly taken from his usual work of repairs and boiler cleaning and put to tending engines and boilers, he has been paid the rate of wage which such latter work calls for and which is in excess of the pay he receives when at the former class of labor. Beyond a doubt the cleaning of boilers is hot and very dirty work and $1.46 appears a very small day'spay for the performance of it. McCarron has frequently to be in charge of two or three men and receives only 6 cents per day more than they do. Is it not fair to assume that the man who directs should get more than 36 cents per week over the men who are directed?

The Company, through Mr. Muirhead, seem to have little to say with respect to this case. It was admitted the work of cleaning boilers was dirty but nothing was said by this witness that would indicate the claim made on behalf of McCarron was an unfair one. This may have been an oversight on Mr. Muirhead's part, but should not now be pleaded to the prejudice of McCarron. It may be safely inferred, however, that McCarron cannot be classed as a skilled laborer in the same sense as the underground repair men, nor could he, if called upon to do so, be able to perform the same grade of work as McLeod and Campbell and the others who have Winfield McInnes as their leading man. On that account and for the further reason of the trend of the evidence, I cannot uphold the Lodge's claim of $1.85 per day for this man, but strike a medium and recommend that his pay should be increased from $1.46 to $1.65 per day of ten hours.

The second case concerns two men, Arthur Cooke and John D. Cameron. These men are employed as fanmen at No. 3 mine, they work on twelve hour shifts opposite to each other. From the evidence, it seems their work consists in the main in constant attendance on their engine and the principal feature of it is its monotony. The job under the law requires the holders to be possessed of certificates of competency. Cooke and Cameron's pay is at present $1.46½ for twelve hours. The Lodge has asked on their behalf $2.00 for the same time. The Company take very strong exception to this case, and claim that it is work suitable only for broken down or worn out men and was given to Cooke and Cameron "simply because they made application, and if they are able to perform other duties there is a good job open for them." Mr. Muirhead further stated that a boy of ten years could do equally as well the work that is necessary.

Taking this matter into long consideration and viewing it as I have from every aspect, and with a full knowledge it involves upon me, I am led to the conclusion, that in a spirit of fairness I cannot do otherwise but recommend that the prices for this class of labor remain as at present, but this recommendation is not to be treated as a precedent for future demands

by the Lodge or individuals employed at it, for an increased pay in respect to it.

The third case. This relates to a demand for an increase of pay for Charles Ronney, a carpenter, from $1.40 plus 22 per cent. to $1.60 plus 22 per cent. The evidence goes to show that Ronney has been engaged for fifteen years or more at the carpenter trade, he works side by side with two others who receive $1.60 plus 22 per cent. and does exactly the same class of work as they perform. He swears he is equally competent as they, working at finishing houses, making trolleys, wood wagons, mine cars, etc., he swears also the work is all alike, that of one being no better or worse than the others. The witness Anthony Johnson, corroborates Ronney's testimony in nearly every particular and swears Ronney is a competent and efficient carpenter and conscientiously says that his present rate is inadequate for his services and not in accordance with other carpenters in the employ, who receive $1.60 plus 22 per cent. per day, and further from his knowledge of Ronney's ability and because he does exactly the same class of work as the other two referred to he should receive the same wage as they. The Company make reply to this by stating that Ronney is not a tradesman and name him as a "handy man" and in the same class as ten others. Mr. Muirhead swears that Ronney is on a par with the ten men referred to and that they are not skilled workmen. Inasmuch as Ronney is not in Mr. Muirhead's department, not much credence should be given to the latter's evidence. It was evidently made in good faith but must of necessity be largely hearsay and not from a personal knowledge of the facts. That Ronney "is" a tradesman in the broad sense of the word can hardly be doubted, and to classify him with the box repairers on the bank heads is unfair. The telegram from the general manager herein before referred to contains this clause "Charles Ronney's claims will be considered when work is resumed as well, and if he is entitled to the wage he requests, the same will go into effect from the 16th inst (i. e., August, 1907)." The question then arises, has the Lodge proved that Ronney is entitled to the wage he requests, or should the mere ipse dixit of the Company be taken that he is little better than a wood butcher? It strikes me the only fair and tenable ground for me to stand on with respect to this third case is to recommend that Charles Ronney receive a daily wage of $1.60 plus 22 per cent. and I so recommend accordingly.

The fourth case, as stated in the application, "is in respect to an advance on wages for Wilson Demmings, car inspector." Here is a man who has been in the employ for fourteen years, sober, painstaking, careful and industrious with the lives of the travelling public and valuable rolling stock committed to his care, a letting up of vigilance on his part would result in loss of life and property and yet his pay only amounts to the meagre sum of $1.58½ per day. He swears that during all the time he has been car inspector, there has never been a case where an accident has occurred through any neglect on his part, he also swears he has tried on various occasions to get consideration by way of increased pay and they (the Company) gave him the impression they would consider it favorably. Demmings' evidence is reinforced in a most convincing way by that of George Watt, I. C. R. car inspector at Springhill Junction, who among other things says, that Demmings' duties are practically the same as the duties of a car inspector on the I. C. R. For such work as he (Demmings) has to perform, they would receive $2.00 per day on the I. C. R. for ten hours, the witness also testified that considering the duties Demmings is called upon to perform, the sum asked ($2.00) is quite reasonable.

The Company, as in Ronney's case, set up the plea that Demmings is being sufficiently paid already, and Mr. Muirhead who, although he testified to having nothing to do with Demmings, not being in his department, sought to break down the weight of Mr. Watt's evidence by making a comparison of the work of the latter with that of Demmings, which is not the case in point at all. Watt is the head car inspector at the Junction and receives 24 cents per hour and extra pay for overtime and night work. The proper comparison should be with men under Mr. Watt who receive 20 cents per hour and for night work time and a half, and whose work is identical with that performed by Demmings.

The evidence tendered by the Lodge in support of this claim is to me so convincing that I have no hesitation whatever in arriving at the decision that they have made out a case. I accordingly recommend that Wilson Demmings shall have his present rate of wage of $1.58½ per day increased to that of $2.00 per day of ten hours.

THE DETERMINATION OF COBALT AND NICKEL.

By W. K. McNeil.*

So for as the Cobalt district is concerned, the principal minerals of which nickel and cobalt are essential constituents are:

Niccolite.—Arsenide of nickel, Ni As.
Smaltite.—Diarsenide of Cobalt, $Co\ As_2$.
Millerite.—Sulphide of nickel, Ni S.
Cobaltite.—Sulph-arsenide of cobalt, Co As S.
Erythrite.—Cobalt bloom, $Co_3\ As_2\ O_8 + 8\ H_2\ O$.
Annabergite.—Nickel bloom, $Ni_3\ As_2\ O_8 + 8\ H_2\ O$.

The following method of analysis has been found useful in the routine developed after a considerable experience in handling Cobalt ores.

Procedure.—Weight out 0.5 to 1 gramme of finely pulverized ore. The amount taken depends upon the percentages of nickel and cobalt present. Decompose by adding nitric, hydrochloric, and sulphuric acids. Not more than 3 to 5 c.c. of sulphuric acid is to be added, as it is used here as an indicator. If an excess is used it will interfere in later operations. Evaporate to white fumes, cool, dilute and filter.

The fifth and sixth groups are now precipitated by H_2S, after the solution is thoroughly reduced by SO_2 directly, or by adding sodium sulphite. Care must be taken to have the excess of SO_2 driven off and also to pass the H_2S through the solution for some time, especially for ores containing a large amount of arsenic, such as niccolite and smaltite. If the solution is kept hot while the H_2S is being passed in, the precipitation is much more rapid and complete. The H_2S may be passed into a cold solution and heat applied gradually. The solution should now be boiled to expel the excess of H_2S. Filter and repeat the precipitation as it is important that all arsenic be removed from the solution.

---

* Manager of the Canadian Laboratories, Toronto.

The next step is to remove the iron and alumina by first oxidizing with a small quantity of nitric acid or sodium peroxide, and adding ammonia slowly to the boiling solution. If care is taken to have the solution completely oxidized and the precipitant added slowly, the nickel and cobalt will not be carried into the precipitate to any extent. Wash the precipitate thoroughly with hot water and re-dissolve and re-precipitate. This may be repeated until the filtrate does not indicate cobalt or nickel.

Concentrate filtrates and add enough $(NH_4)_2\ SO_4$ to have the total bulk of the solution in the proportion of about 3 grammes for each 0.1 to 0.2 grammes of cobalt and nickel present. If too much sulphuric acid is added in the first solution of the ore this operation is interfered with.

The nickel and cobalt are now precipitated by a current of 0.7 amperes (maximum) the solution being at the temperature of 70 degrees C. The time required is two to four hours according to temperature.

If the cathodes blacken it means that the current is too strong or that arsenic has not been completely removed.

After weighing the cathodes, dissolve off the deposited nickel and cobalt with nitric acid using as small a quantity as possible. Neutralize with KOH, make acid with acetic, and add a concentrated solution of potassium nitrate, stirring for some time. Enough acetic should be added to make noticeable the evolution of nitrous fumes after the addition of potassium nitrate. Allow the solution to stand in a warm room for 24 hours. Filter and wash the precipitate of $Co_2(NO_2)_6$.-$6KNO_4$ which should be yellow and crystalline with 10 per cent. solution of potassium acetate then with alcohol. It may be now treated with H_2SO_4 and converted to $3K_2\ SO+2CoSO_4$ and weighed, or dissolved and electrolyzed under the usual conditions and with the usual precautions.

SOME FEATURES OF SILVER ORE TREATMENT IN MEXICO.

Part II.—Theoretical Considerations.

(Abstract of paper read by W. A. Caldecott, B.A., F.C.S. before the C. M. and M. Society of South Africa.)

The following discussion is rendered imperfect on account of the non-arrival of a parcel of Mexican silver ore, which was to be tested to develop and confirm the tentative conclusions arrived at from an examination of the properties of artificially prepared silver sulphide. It is probable that since the mineral silver sulphide is coarser and more compact than the artificially prepared compound its dissolving in cyanide solution is slower, thus allowing more time for secondary reactions to proceed.

The primary reaction in the dissolving of silver sulphide from its ores may be taken as

$$Ag_2S+4NaCy=2NaAgCy+Na_2S-(1)$$

When, however, a certain amount of silver has been dissolved an equilibrium is established. How far the reaction has proceeded before this equilibrium is attained, depends upon the amount of soluble sulphide of any kind in solution and the amount of free cyanide present.

This is illustrated by the following table, showing results from a series of argentiferous sodium cyanide solutions of the strengths stated, 100 c.c. of each of which was titrated with 0.1 per cent. sodium sulphide solution until a brownish coloration was pust produced. A deduction of 0.05 c.c. was made from each reading, so as to give the amount of sodium sulphide that could be added without reacting upon the silver present.

Table A.

Per cent free cyanide	Silver present mgrms per litre	Na_2S required mgrms per litre	Equiv. sol. Ag. present (as Ag_2S) mgrms per litre
0.50	490	5.3	14.7
0.40	392	4.4	12.2
0.30	294	3.1	8.6
0.20	196	2.0	5.5
0.10	98	1.0	2.8
0.05	49	0.7	1.9

An inspection of the foregoing table, in which milligrams per litre may be read as grams per metric ton, shows that the amount of silver sulphide capable of being dissolved as the soluble double alkaline cyanide is approximately proportionate to the amount of free cyanide present, but even with 0.5 per cent. solution the quantity of dissolved silver is less than 0.5 ounce per 2,000-pound ton. Further, the introduction, through presence of a free alkali or otherwise, of soluble sulphides into the argentiferous cyanide solution from any mineral or other source will result in the precipitation of silver already disolved.

The fact that dissolved silver and other than very small amounts of sodium sulphide cannot exist simultaneously in the same solution serves to explain why working solutions do not show more than traces of sodium sulphide when sulphide ores are being treated. With solutions low in silver it is difficult to filter off the very finely divided precipitate formed on addition of sodium sulphide solution.

In practice, many ounces of silver per ton existing as sulphide can be dissolved. This is explained by the occurrence of secondary reactions, which show the conversion of soluble alkaline sulphide first formed, into other compounds which do not preclude the further solution of silver. These secondary reactions several of which no doubt proceed simultaneously, are:

(a) $2Na_2S+2O_2=Na_2S_2O_3+Na_2O-(2).$
$Na_2S_2O_3+Na_2O+2O_2=2Na_2SO_4-(3).$
(b) $Na_2S+NaCy+O=NaCyS+Na_2O-(4).$
(c) $Na_2S+PbO=PbS+Na_2O-(5).$
$PbS+NaCy+O=NaCyS+PbO-(6).$

The foregoing reactions, when carried to completeness, all involve absorption of oxygen, whereby the utility of aeration may be accounted for, apart from its accelerating the solution of any metallic silver or gold present in an ore under treatment. Reaction (a) proceeds more rapidly than does (b), and since it does not involve destruction of cyanide and since it produces in the first stage sodium thiosulphate, (itself a silver solvent) it may be considered the most desirable result of aeration.

Apart from any re-formation of PbO, nearly as much lead as there has been silver present as sulphide is required to carry equation (5) to completion.

A study of the molecular weights involved in equation (1) shows that the silver requires nearly its own weight of sodium cyanide to discolor it, so that the consumption from this cause alone with 500 gm. silver ore would be nearly a pound of sodium cyanide per ton.

This feature of high cyanide consumption renders the field for cyanide regeneration more promising than with banket gold ores. Although oxygen does not play the direct part in dissolving the silver that it does in gold ore treatment, yet its importance in permitting solution to proceed, and the present necessity for the tedious process of repeated agitation and aeration, appear evident.

A series of experiments demonstrated, by the trivial amount of silver in the precipitate, how effectual is the presence of lead in preventing precipitation of silver, and consequently in permitting the dissolving of silver sulphide to proceed in spite of the concurrent formation of solubel sulphide.

SUMMER EXCURSION.—CANADIAN MINING INSTITUTE.

The following is a provisional programme prepared by Mr. Mortimer Lamb, for criticism.

SUMMER EXCURSION. C.M.I. 1908.

Time Table.

August 24. Leave Quebec in afternoon.
25. Arrive Sydney, midnight.
26. Visit Dominion Iron & Steel Company's works and Dominion Coal Company's mines (arrangements to be made by The Nova Scotia Mining Society).
28. Stellarton, 7.20 a.m.
29. Return, via St. John to Sherbrooke.
30. Arrive Sherbrooke 5.30 a.m., and leave for Thetford by Quebec Central.

Sept. 1. Leave Sherbrooke by C. P. R. at 3.30 a.m. arriving in Montreal at noon.
2. Leave Montreal for Toronto 10.00 p.m.
3. Arrive Toronto 7.00 a.m., leave for Niagara Falls.
4. Reception and entertainment of visitors in Toronto by the Directors of the Toronto Exhibition. Leave Toronto 11.30 p.m. for North Bay.
5. T. & N. O. train for Cobalt.
6. Leave Cobalt 5.00 p.m. (?) connect with train, at North Bay 10.35 p.m. Arrive Sudbury 12.50 a.m.
7. Arrive Sudbury 12.50 a.m.
8. Moose Mountain (?) Port Arthur (?).
9. Leave Sudbury 5.35 a.m.
10. Arrive Winnipeg 9.50 a.m., leave 11.50.
11. Arrive Medicine Hat 11.40 a.m., and proceed to Lethbridge by special train. Leave for Frank in the evening.
12. Visit Frank and Blairmont.
13. Fernie.
14. Special train leaving early in the morning for Moyie. Leave 1.55 for Kootenay Landing. Arrive in Nelson 7.15. Arrive Rossland midnight.
15. Rossland mines.
16. Leave Rossland 8.40 a.m. Arrive Smelter Junction 9.35. Leave Trail 7.20 p.m. Arrive Nelson 10.30 p.m.
17. Visit Bonnington Falls, etc., and reception at Nelson.
18. Leave Nelson 9.45 a.m. Arrive Grand Forks 2.50 p.m. Arrive Greenwood 4.25 p.m. (visits to the different mines in the Boundary district will necessitate chartering a special train).
20. Leave Greenwood (?) 3.20 p.m. Arrive West Robson 11.05. p.m.
21. Arrive Arrowhead 1.00 p.m. Arrive Revelstoke 2.45 p.m.
22. Arrive Vancouver 1.30 p.m. Arrive Victoria 8.30 p.m.
23-24. Meeting Victoria.
25. Arrive Vancouver 8.00 a.m. Leave Vancouver 3.15 p.m.
26. Arrive Banff 10.00 p.m.
27. Leave Banff 10.00 p.m.

Oct. 1. Arrive Montreal 8.25 p.m. Arrive Quebec 3.20 p.m.

BOOK REVIEWS.

A Treatise on Mine-Surveying, by Bennett H. Brough, Thirteenth Edition, revised. Pages XVI + 372. Price, cloth, 7s. 6d. Charles Griffin & Company, Limited, Exeter street, Strand, London. 1908.

As indicated on the title page, Mr. Brough's volume has passed through thirteen editions. This, in itself, is evidence that the book occupies an important place as a standard text book.

The first chapter is general. The importance of mine surveying in its relation to the industry is dwelt upon and a practical classification of mineral deposits, for surveying purposes, is given. For instance, under "tabular deposits" are included mineral veins, beds and seams. "Irregular deposits" comprise masses, stockworks, and pockets. The former class is defined as those in which two dimensions predominate.

The second chapter takes up the measurement of distances and describes the chain, the rod, steel-bands, needle surveying are treated in two chapters. The German dial, invented in the seventeenth century by the measuring wheel, pacing it. Needle and fixed Balthasar Roessler, is the subject of Chapter VII. It is noted that the use of the dial is becoming much less common and the theodolite is gradually replacing it. It is still found useful in narrow workings.

The theodolite (or transit) and its use underground and on the surface are set out in Chapters VIII, IX, and X. Chapter X includes specimen field notes of the survey of an American mining claim.

In discussing mine plans, reference is made to the accuracy of the inspection plans required by law in the Pennsylvania anthracite districts. These maps are on a scale of 100 feet to an inch. The working maps are usually on a scale of 200 to 300 feet to an inch. Topographic and culture features are shown in different colors of ink. The survey lines are plotted with a vernier-protractor, or a protractor of very large size, and the results are checked by latitude and departure calculations.

In Belgium and in France mine plans are required by law to be laid down on a scale of 1 : 1000. In Prussia the scale varies from 1 : 500 for metalliferous mines to 1 : 1600 for collieries. Colliery plans in Great

Britain must not be less than 1 : 2500. In Pennsylvania the scale of plans for anthracite mines is 1 : 1200. The Swedish Mining Act demands that all plans and sections must be drawn on a scale of 1 to 800, and must be made in conformity with a Normal Map, drawn up by the Mining Department.

A chapter on magnetometric surveying, in which the various types of magnetometer are fully described, is followed by a section on photographic surveying and its application to mining work. The use of photographic methods in the Yukon, in the Kootenay mining district, and in the Crow's Nest coal country is cited.

Two appendices, the first giving 163 examination questions chosen from British papers and the second presenting a bibliography of the principal treatises published in mine surveying, conclude the volume.

Naturally this last edition is an improvement on its predecessors. Throughout the volume there is diffused much general information. Practice in foreign countries is given due notice.

Diagrams are interspersed lavishly through the text. The few half-tones that appear are not excellent.

Mines and Minerals of the British Empire, by Ralph S. G. Stokes, Late Mining Editor, "Rand Daily Mail," Johannesburg, S. A.—Demy, 8 Vo. Numerous Illustrations. Price 15s. net. Published by Edward Arnold, 41 & 43 Maddox street, London W. 1908.

In his tour of the British Empire, Mr. Stokes covered more than 35,000 miles. Only twice did he touch foreign territory. Only once was he within one hundred miles of any important mining field that was not on British soil. The journey was undertaken on behalf of the Mining World, of Chicago, and a group of British dailies. Much of the material now cast into permanent form appeared in the shape of articles during the author's pilgrimage. But by the co-ordination of these articles and the addition of supplementary information, Mr. Stokes has produced a readable and intrinsically valuable volume.

We welcome anything that tends towards establishing bonds of sympathy between workers in the various countries that make up the British Empire. Indeed, we hope some day to see an Imperial Mining Institute with branches all over the globe and headquarters in an airship. Until there are regular currents of communication and constant interchange of ideas between English speaking mining districts, progress will be uneven and often slow.

The fundaments of Mr. Stokes' book are sound. To treat the mines and minerals of the British Empire as a whole is a large and bold idea. To complete the task creditably in one volume argues clear prospective, strong judgment, and much labor.

Not as a newspaper "copy-mill" does Mr. Stokes take up his work. Being a practising mining engineer himself, he has been able to observe and describe the things that most interest his technical brethren. As an experienced journalist he has given us his observations succinctly. Geological, mineralogical and other technical details are given their proper value in relation to economic, political, and social conditions. Herein, perhaps, lies the chief merit of the book before us and, therefore, the principal result of the journey.

It is out of the question to attempt a complete review of the ground taken up by the author. But it will be more profitable, because less wearisome, to single out a few characteristic sections and confine our attention to these.

Starting from South Africa, Mr. Stokes' pilgrimage led him through Ceylon, famous for its graphite and gems, through the Indian Empire where mica, manganese, coal, gold, iron, and almost the whole gamut of commercially important minerals are found, through the Malay States whence comes the world's principal supply of tin, and where, as in India, devices as old as civilization are used side by side with modern machinery. Thence his way was taken through the gold, copper, silver-lead and zinc fields of Australia, the gold, copper and tin districts of Tasmania, the gold and coal of New Zealand, and Canada from British Columbia to Quebec was covered last.

Amongst the serious gaps in his itinerary the author notes Mysore, Queensland, Klondyke and Rhodesia. We must add to these another omission, unmentioned by Mr. Stokes. Nova Scotia is given but incidental notice in the volume. It was not visited, nor is apology offered for the scant paragraphs with which its magnificent coal and its historic gold and iron areas are dismissed. This serious hiatus, due no doubt to hurry and lack of time, should have been specifically explained in the preface. We may pardon Mr. Stokes for not visiting the Klondyke, but it is hard to imagine a sufficient excuse for not including Nova Scotia in his itinerary.

Introductorily the magnitude and vital importance to the Empire's mining industry is emphasized by means of tabular statements and a few crisp paragraphs.

"The prospector's memorable decade of 1882-1891 (the first five years of which saw the birth of the Rand, Mount Morgan, Sudbury, Waihi, and Broken Hill)," is contrasted with the past decade.

"The influence of the mining industry upon the growth and welfare of the British Empire is most fully exhibited by the history of the several colonial territories which it has raised to the forefront of commercial nations from the obscurity of sterile wilderness." Applying this dictum to Canada we find that it needs modification. It is true that, but for the gold of the Yukon, that territory would be yet terra incognita. But in Nova Scotia, in Quebec, in Ontario, in Alberta and in British Columbia, the industries of mining, lumbering and fishing are carried on often in the same district. The conformation of Nova Scotia's coast line is such that but few of her important mines are more than a dozen miles from salt water and good harborage. The mines of that province and of Quebec are drawn to a considerable extent from the agricultural class. There is hardly a mining district in Ontario in which farming is not actively pursued. Throughout Alberta and Britsh Columbia the same favorable climatic and physiographical conditions obtain. Canada is blessed with a total absence of those sterile wildernesses of which, in other countries, mineral wealth is the only saving feature.

The annual mineral yields of the British Empire aggregate the tremendous total of, roughly, $1,000,000,000. "In whatever direction" writes Mr. Stokes, "and to whatever degree the popular conception of its financial aspect may be at fault, the mining industry unmistakably appears in a light that is favorable without

reservation as a field of employment for highly remunerated workmen, and the support of the most prosperous laboring communities in the British Empire."

Chapter I is a cursory view of mine labor in widely separated parts of the Empire. The Sudbury labor position is remarked upon as being "industrially sound, but political deplorable." It "reflects one of the ugliest features of Canada's liberal immigration policy." Day's pay for skilled labor ranges from $2 per day, the rate obtaining in Bendigo and Ballarat, to $5 per day in the Gold Coast mines of Western Africa. Canadian rates are uniformly higher than those of any other British country.

As we read chapter after chapter we come upon other themes most worthy of expansion. For instance, the financial assistance given to deserving mining ventures by the Victorian and Western Australian governments should indicate a line of action for Canadian administrations. Under the Mines Department Act the Victorian government advanced a company (that had already expended $1,000,000, on plant and operations) the sum of $40,000 for additional prospecting, at the same time demanding repayment of the first profits and securing itself by a mortgage on the lease and one of the company's plants. In Western Australia there are twenty-nine state batteries and twenty-four state cyanide plants. The treatment charges are so regulated that the year's current expenses for the whole state are approximately balanced by receipts. The system has its defects, but undoubted good has resulted in the speedy development of new districts.

The government of New Zealand, in 1901, reserved 8,000 acres of coal land near Greymouth (South Island) for state operation, These, under the direct control of the Minister of Mines, have been financially successful. The miners are registered as an industrial union and work is carried on under an agreement entered into by the union and the manager. The government has encouraged its employees to build homes for themselves on reserved portions of the township. However, Mr. Stokes assures his readers that the nationalization of the mining industry is "still far below the political horizon."

The marked increase in the scale of milling operations on the Rand gives food for thought. In December, 1898, there was not one plant milling over 50,000 tons per month. There was but one milling between 40,000 and 50,000 tons. But, of 62 plants, 42 were handling under 10,000 tons. Contrasting strongly with this is the record for December, 1907. In that month there was one plant of over 50,000 tons, four between 40,000 and 50,000 tons, and only 14 of 10,,000 tons capacity. Whereas plants dealing with more than 20,-000 tons per month constituted only 9 per cent of the total in 1898, they now represent 97 per cent.

In the columns of the "Canadian Mining Journal" the metallurgical progress of the Rand has been noted and analyzed on several occasions. Mr. Stokes makes clear presentation of the principal operating causes of this progress. All of his chapters on the Rand, indeed, are notable, but space will not permit of further notice here.

Of Canada Mr. Stokes shrewdly remarks that it has as yet failed to win a lofty place as a mining country, not because of mineral poverty, but because its energies have always been applied to the exploitation of its agricultural resources. The dissimilar methods of ore-valuation adopted at Ottawa and by the provincial departments are commented upon.

"A particularly favorable feature of Canada as a mining country is the lack of excessive centralization; its productive fields are diverse in character and wide in distribution. Amongst the mineral occurrences are the greatest deposits of nickel, asbestos, and placer gold, and the richest silver field in the world."

Nova Scotia's gold mines are thus spoken of: "The cause of the field's retrogression is more freely attributed to inefficient mining methods, to the unsound influences of granting small mining areas, and to the lack of any laws compelling holders to operate their mines, than to the deficiencies of mineralization."

The free circulation of the careful and trustworthy maps and reports of the Geological Survey is the subject of favorable comment.

Mr. Stokes' chapters on Cobalt, Sudbury, Quebec and British Columbia will stand inspection even by a Canadian mining man. They are not beyond criticism, but they are clear, incisive and honestly descriptive.

We would willingly dilate further upon the "Mines and Minerals of the British Empire." but we must respect the reader and bow to the printer. It may, however, be permitted to conclude by offering Mr. Stokes our warm felicitations upon his courage and vigour in successfully attacking so large and imperial a theme. From those of our readers whose privilege it may be to read the book we invite comment and criticism. This we do because we believe that it will at once assume a niche in every well conditioned library.

Hints on Amalgamation and the General Care of Gold Mills—by W. J. Adams, E.M. Illustrated. Second Edition, Revised and Enlarged. &120 pages. Price $2. The Mining and Scientific Press, San Francisco, 1908.

Ten years ago the first edition of this book was brought out. Years before, coming to California as a young mining school graduate, the author soon discovered that his technical education had only taught him chemistry and scientific mechanics in general. He lacked practical rules for the application of his knowledge. His real education then started at the bottom of the ladder in a gold mill. These rules, the result of "bitter experience, extending through many years." he set down in this little volume.

Now, ten years after the first writing, another edition has been brought out. Very few changes have been made in the text, but an appendix deals with the more salient changes in gold milling.

The book iwsritten by a practical man for practical men. It will, no doubt, fulfil its mission.

A Dictionary of Spanish and Spanish-American Mining, Metallurgy and Allied Terms—by Edward Halse, A.R.S.M. 380 pages. Price 10s. 6d. Charles Griffin & Company, Limited, Exeter street, Strand London, 1908.

Griffin's Mining Series has long been known to mining men. This recent addition will prove quite as useful as its predecessors.

The impression exists that Spanish is an easy language to acquire. This impression is modified when the young engineer, who has neglected to include Span-

ish in his studies, finds himself obliged to pick up a working knowledge within the least possible time limit. To one in such a predicament and, indeed, as a useful companion to the practising engineer whose reading or whose engagements bring him in touch with mining in Spanish-speaking countries, the dictionary should be a boon.

As in German, French, and Italian, so in Spanish dictionaries, it is wonderfully difficult to find the technical terms that one needs. And if these terms happen to be colloquial variants of standard words, the search is all the more hopeless.

In this dictionary all provincial terms are referred back to standard terms. In some instances lists of synonyms and equivalents in French, German and in some instances, Portugese, are given.

While Mr. Halse's dictionary is by no means the first of its kind, it is, perhaps, the most complete and useful.

INDUSTRIAL PAGE.

Underground Wire Rope Haulage.—The Broderick and Bascom Rope Company, St. Louis, Mo., U. S. A.— This most creditably done pamphlet tells of the successful application of underground rope haulage in the workings of the Coal Valley Mining Company at Sherrard and Cable, Illinois. The illustrations are exceptionally good. The letter press could hardly be excelled.

An outline of the three general methods of wire rope haulage is followed by a description of the tail rope systme in use in the Coal Valley mines.

At the Cable mine a tail rope system extending into the workings for a mile and a half was the means of immediately doubling the output at one-half the cost of the old operations. This was possible despite the heavy grade of the main tunnel.

A comparison of mule haulage and wire rope haulage, shows that the costs of installation are about the same. But there is a daily saving in favor of the wire rope system on an output of 1,000 tons per day, of $130.

Bulletin 1062, Allis-Chalmers Company, Milwaukee. —The principle feature of the equipment of the Milwaukee Northern Railway is the fact that the motive power of the road is furnished by gas-engine-driven electric generating units of a size heretofore unknown for purely traction service.

The total completed trackage is 30 miles in length and 82 miles are yet to be completed.

The power house at Port Washington, Wis., is situated on the water front. Two buildings, one for the producers and one for the engines, generators, switch boards and protective apparatus, make up the power plant proper. Both buildings are of concrete, steel, and brick and are fifty feet apart. The gas supply main is run outside and along the entire length of the power house from the producer plant.

The generating units are three in number, each of 1,000 kw. capacity. Each unit consists of a twin tandem horizontal double acting Allis-Chalmers gas engine direct connected to a 405 volt 25 cycle Allis-Chalmers alternator. Both engines and generators were designed with large overload capacities, the engine being capable of developing upwards of 2,000 h.p., and the generator having a corresponding capacity. Each engine has four cylinders, 32 inches in diameter by 42 inch stroke, and operates at 107 revolutions per minute.

The valve gear is of the standard Allis Chalmers cut-off type and the engine operates with constant compression, insuring smooth running under highly variable loads.

The engines, being twin tandem, will start from any position. All wearing surfaces are arranged for a continuous oiling system, and the cylinders are lubricated by carefully timed admission of the cylinder oil.

The distinctive features of the engines are the extreme simplicity of design, the solidity of construction, and the quiet operation.

The gas producers operate on the Loomis-Pettibone system. The gas is delivered into a holder of 30,000 cubic feet capacity. The normal rating of the present plant is 4,00 h.p., and it has a capacity of 25 per cent. overload for five hours' duration.

Hocking Valley bituminous slack coal, registering 11,500 B. T. U., is the fuel ordinarily used. The downdraft principle is used, the air being admitted through a charging door at the top of each producer. The volatile matter and distillates are thus drawn through the deep bed of incandescent fuel and gasified. Gas is obtained containing 80 per cent. of the heat units possessed by the fuel. Reverse runs of steam are occasionally made for the purpose of breaking up the fuel bed.

The electrical features of the equipment are briefly: Three phase current is generated in the power house at 405 volts and 25 cycls by direct coupled alternating current generators, each of 1,000 kw. normal capacity. These machines are of a special type developed by Allis-Chalmers Company for use with gas engines.

A New Coal Mining Machine For Low Veins. For several years the use of the Sullivan Continuous Cutting Electric Chain Coal Mining Machine has steadily increased, as operators in various fields of this country have learned to appreciate its advantages. The success of this type has been such as to warrant the development of a similar machine for mining coal, both in rooms and on long wall faces, in thin seams.

The Sullivan Low Vein Room and Pillar Mining Machine, designated as "class CE-6," is mounted upon a steel shoe or frame for convenience in transportation and for making its first cut. In making the first or rib cut, the machines moves forward out of this frame, which is cut away at the left-hand side. The rear or anchor jack is then set in the right-hand corner of the room, at the other extremity of the working face. The machine propells itself across the face on a feed chain stretched between these two jacks, cutting the entire room at a single operation. The accompanying illustration shows the machine in the above position, with the two jacks referred to.

It will be noted that the machine travels on a sheet steel plate, occupying the least possible space. No rollers or rails are required on which to run the machine while making this cut. It will also be noted that this is virtually an adaptation of the long wall principle to room work. The machine is not withdrawn from the coal and moving it over by hand for the next cut; but as there is no frame or pan behind the machine, as in the case of the breast type, it occupies but one-half as much space as the latter in front of the coal, thus allowing props to be permanently set within six feet of the face, and reducing the distance which the coal and

FIG. 3.

SULLIVAN CONTINUOUS COAL CUTTER AT THE END OF THE FIRST OR SUMPING CUT

coal after making the first or sumping cut, until the left rib is reached.

This method accomplishes notable economies in mining and in handling the coal. Not only is much time and labor saved that is ordinarily employed in backing the ordinary type or breast machine out from the machine cuts on the bottom, at all times closely following the contour of the floor, no coal is left after it, to be raised by hand, nor are sprags or ribs left at the rear of the cut to interfere with blasting to the best advantage.

The machine has been carefully designed to secure

strength, durability and at the same time low height and compactness of the working parts. The motor is debris must be moved by the loaders. As the Sullivan placed horizontally instead of vertically, as is usual in the ordinary machines of this type, and is wound for 210, 250 and 500 volts, direct current, as required by and the power truck 900 pounds. The motor develops 30 horse-power at 1,125 r.p.m.

This coal cutter has proven very satisfactory to operators on account of its high cutting speed, from 16 to 39 inches per minute, small bulk and ease of manipulation and carriage. It is capable of operating on

FIG. 4.

SULLIVAN ROOM AND PILLAR MACHINE, MAKING CONTINUOUS CUT ACROSS THE FACE OF A ROOM.

mine conditions. When cutting, the machine stands 21 inches high and occupies a space of five feet three inches between the coal and props. The kerf or height of mining is four and one-half inches, and the depth of cut ranges from 63 to 75 inches. The machines is moved from place to place in the mine on a special self-propelling electric trunck. When on this truck the pitches of 30 degrees when rooms are driven across the pitch, and of 12 degrees when rooms are driven straight up the pitch. As indicating the capacity of this type, it may be mentioned that at the mines of the Gay Coal & Coke Company, Logan County, West Virginia, a Sullivan Class "CE" machine has undercut, on a long wall face, 377 feet to a depth of six feet one inch, in eight

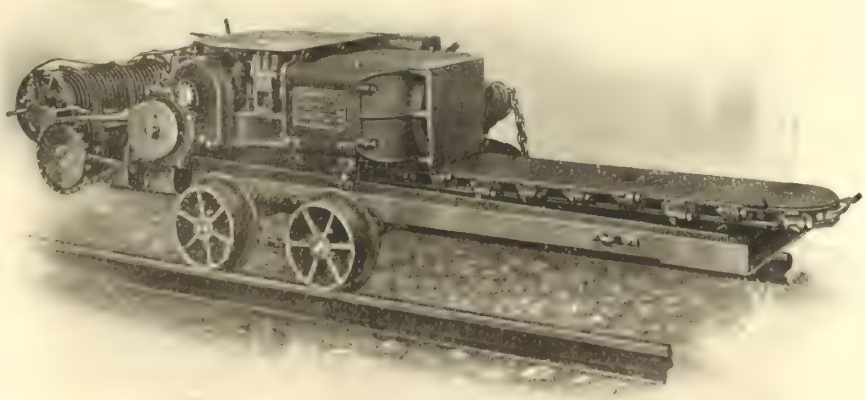

FIG. 5.

SULLIVAN LOW VEIN ROOM AND PILLAR ELECTRIC CHAIN MINING MACHINE ON POWER TRUCK FOR TRANSPORTATION FROM ROOM TO ROOM.

machine stands 30 inches above the rails, although if desired, a truck is furnished with drop axles, reducing the total height to 27 inches. The machine performs all operations under its own power, including loading and unloading from the truck, so that hand labor is reduced to the minimum. The machine weighs 3,100 pounds, and one-half hours, thus producing over 500 tons of coal. While these machines naturally make a better showing in wide rooms, experience has shown that they are also much more economical than the breast cutter in narrow rooms and even in entries.

NOVA SCOTIA.

Glace Bay.

Outputs of Dominion Coal Company for May:—

No. 1	49,399
No. 2	65,594
No. 3	36,271
No. 4	36,759
No. 5	49,623
No. 6	22,544
No. 7	3,749
No. 8	19,851
No. 9	34,770
No. 10	14,028
	332,588

In its issue of the 1st inst., the "Halifax Herald" gives prominent place to a letter signed by H. C. McKenzie of Stellarton, throwing doubt upon the bona fides of the award of the Board of Conciliation under which the miners of the Dominion Coal Company are now working, and intimating that the members of this Board foisted upon the P. W. A. an arrangement which is really a decrease in their wages, while maintaining to the Government and the country at large that it was an increase of somewhere in the neighborhood of $70,000 per annum. This same gentleman makes several statements supported by figures borrowed from the Annual Mines Report, which by the way covers an entirely different period from that covered by the award under discussion, and by a process of dwelling on the concessions given by the P. W. A. and a slurring over of the increases granted by the Coal Company, he succeeds in presenting just that sort of mischievous misrepresentation of facts that impresses the superficial reader. His statements are, however, utterly untrue in every instance, there being not even one that cannot be directly traversed and categorically contradicted. The facts are these. After allowing for the increased price of house coal, the increased price of powder and the decreased pillar rate, the net gain to the men is between $6,,000 and $7,000 per month, or at the lowest computation $80,000 per annum. We have these figures officially from the Coal Company's officials, and they are facts, not malicious fiction. The true inwardness of Mr. McKenzie's tirade comes out when he falls foul of the Lemieux Act, because, forsooth, it is "a creation of the present Government" and of the Grand Secretary of the P. W. A. because he voted for a certain political party. We often wonder whether there is anything in Canada, in business, religion, citizenship, or social intercourse, anything in heaven or earth that is not tainted with politics. It always creeps out, and in the most unexpected quarters. We feel inclined to echo the Gilbertian couplet, that:

It really is astonishing, how nature doth contrive
That every little boy and girl, who's into this world alive,
Is either a little Liberal, or else a little Conservative!

What W. S. G. would have said had he lived in Nova Scotia it would be interesting to know. We recommend Mr. McKenzie to read Psalm 80, sixth verse.

Some very interesting figures are to be found in an editorial in the "Colliery Guardian" of the 22nd inst. which are somewhat disconcerting to those who claim that a diminution of accidents could be effected by a curtailment of the hours worked, or put it the other way, that accidents are more numerous in the closing hours of work than in those of the commencement of work. The following figures are given by Mr. John Gerrard, for many years the Chief Inspector of the Lancashire Coalfield in England. The editorial makes the following remark, which is somewhat apropos of the statements that have been made recently in the local press as to the hours worked in Nova Scotian coal mines. One writer to the local press stated among other wild and whirling words, that the Nova Scotian miner had the unenviable distinction of working the longest hours of any men "outside of the Siberian convicts." The Guardian says: "In Lancashire, the men usually begin to descend about 6 p.m., meals are mostly taken between twelve and two o'clock, at which hour, at a few pits, the men are allowed to ascend; not many, however, avail themselves of this facility to limit their work to eight hours, and the winding of men, in the majority of cases begins about three o'clock." The figures given by Mr. Gerrard are as follows:

NUMBER OF ACCIDENTS.

Hour of Shift	1901	1902	1903	1904	1905	1906	Total	Per cent. of Total
1	19	21	18	24	26	18	126	13.4
2	15	14	16	20	18	27	110	11.7
3	16	11	20	244	18	14	103	11.0
4	20	15	15	18	14	24	106	11.3
5	15	14	22	21	18	18	108	11.5
6	20	20	22	15	16	29	122	13.0
7	15	12	17	17	11	17	89	9.5
8	14	20	11	18	21	18	102	10.9
9	12	10	6	6	10	10	54	5.8
10	1	2	5	2	4	4	18	1.9

The conclusions arrived at from the study of these figures are that the most dangerous hour is the first in the day. This is what one would expect in a mine. The sixth hour appears to be one that has a large proportion of accidents, and after that the proportion decreases. It is therefore very apparent that the bulk of accidents in mines do not occur in those hours which the advocates of the Eight Hours Bill claim to be the ones most dangerous to life, because of the fatigued state of the workers, but they occur before the seventh hour. The Guardian also quotes extensively from some figures compiled by one of the leading indemnity associations in England, which show the same result as Mr. Gerrard's figures, and both of them agree in the peculiar fact that the hour from 11 to 12 a.m. is the one most prolific in accidents. The records of the indemnity company show that this hour is much more dangerous than the first hour of work. The Miners' Eight Hour Day Committee in their report state that they "have failed to obtain any evidence which would associate the number of accidents in any disproportionate degree with the hours in excess of eight spent underground by them, or the districts in which the longest hours are worked." The Guardian points out that there is a real danger if men work to a point at which their perceptive faculties begin to flag and thereby are rendered less acute in detecting danger, but that there is no real evidence to show that this point is reached in a mine within a period of eight hours.

The output of the Dominion Coal Company for May was over 330,000 tons, making their total output to date 250,000 tons in excess of the same period of 1907.

ALBERTA.

Lethbridge.

W. D. L. Hardie, general superintendent of the mines of the Alberta Railway and Irrigation Company has gone east on an extended trip. Mr. Hardie will visit the mines in Nova Scotia where new steel tipples have been erected recently to get in

formation in that branch of engineering. The A. R. & I. Company contemplate the erection of a steel tipple at their No. 5 shaft which is at present being sunk.

Taber.

The Scranton Coal Mines Company Limited with headquarters at Spokane, are opening up a new mine on their property recently acquired. The vein which it is proposed to work is 42 inches thick and is a high grade lignite. Six men are employed driving a tunnel to the cove and the proposition is under the charge of Mr. W. J. Reynolds, mining engineer of Spokane.

In the Supreme Court before Mr. Justice Scott and jury, Joseph Tinsley of this town was awarded $3,152.80 damages against the Canada West Coal Company of Taber, for injuries received in an accident in the mine in August of last year. The plaintiff had his leg broken by a run-away mine car on the tipple of the Canada West Coal Company's mine.

Coleman.

As already reported the strike at Coleman was short lived and there has been no further trouble. Forty new coke ovens will be erected as soon as possible and it is the intention of the International Coal and Coke Company to still further add to their ovens in the near future.

SASKATCHEWAN.

Saskatoon.

The prospecting operations which have been in progress all winter and spring at Eagle Lake have in the meanwhile been stopped. It will be remembered that these operations were carried on by the Provincial Government with a view to finding a cheap and convenient supply of coal for the settlers in the Eagle Lake district. Several trial shafts were put down and coal was found in almost every case, but the veins found were not thick enough to allow of economical working. The expense of timbering was very heavy as the coal vein was overlaid by a soft clay, which required very close timbering to hold up. All timber had to be hauled by wagon for about 90 miles as there is no growth of suitable timber on the prairie in the neighborhood.

It is supposed, however, that there are other veins of coal in this district and it is the intention to continue boring operations at some future time.

Bienfait.

The result of the meetings of the Board of Arbitration appointed under the Lemieux Act to investigate the grievances of the miners employed at the Western Dominion Collieries Company has been that an agreement has been arrived at between District No. 18 of the U. M. A. of A. and the Colliery Company.

A schedule of rates for all classes of labor, both above and below ground, has been agreed to, while contract miners' rates remain the same as at present. The company agrees to the check off system and full recognition of the Union. The question of the price of supplies has also been satisfactorily arranged. Judge Myers acted as chairman while J. R. Crowe represented the company and Frank Sherman the miners.

The investigation under the Lemieux Act, before Judge Dawson touching the miners and the Manitoba and Saskatchewan Coal Company, is still proceeding.

BRITISH COLUMBIA.

Hosmer.

Work is being steadily pushed ahead at the mines and every one is looking forward to the 1st of January of next year at which date the company's agreement with the Crow's Nest Pass Coal Company expires and coal can be shipped.

A large force of men are employed on the coke ovens, but, owing to a dispute with some of the men employed on the ovens, work was delayed for a short time.

Michel.

There has been considerable trouble at the Michel mines recently. A miner by the name of Marchant obtained a job from the pit-boss of No. 8 mine, and received an order for his tools, supplies, etc. When he presented himself for work he was told that his place had caved. Marchant then reported to the Union Committee, who interviewed Mr. Derbyshire, the manager, and Marchant was again refused work. A special meeting of the miners was then called and a vote taken to suspend work until Marchant was given a job. Immediately after this, President Sherman of District No. 18, U. M. W. of A., arrived in Michel and made inquiries why he had not been informed of the suspension of work. The Michel men told him they intended to fight the matter out their own way. The president then pointed out that they were breaking their agreement.

The following day summonses were issued against Chas. Garner, Jas. Douglas and Wm. Whitehouse of the miners' committee, for a breach of the Lemieux Act in inciting the men to strike. These three men were tried before a Justice of the Peace, and the cases dismissed on th grounds that the J. P. had no jurisdiction in this matter.

It was expected by the men that the Fernie miners would strike in sympathy, but these latter continued to work. Eventually another meeting was held and the men decided to place the matter in the hands of their district officers and return to work.

Mr. Hurd, the general manger of the Crow's Nest Pass Coal Company, insisted that the men return to work before he would consider their grievances and sent the District Union the following letter:

President of District No. 18, U. M. W. of A.

Dear Sir:—On the evening of May 15 th, 1908, Jas. Douglas, president of the Michel Local, Chas. Garner, secretary of the same, and Wm. Whitehouse, member of the Grievance Committee, Michel Local, waited upon Mr. Derbyshire, superintendent of our Michel Colliery and requested that employment be given to Henry Marchant.

Upon being told by Mr. Derbyshire that no employment would be given to the said man, he informed Mr. Derbyshire that he would be given until Saturday evening to employ Marchant and if the same was not done there would be no work on Monday. Mr. Garner further said that the mine would lie idle till Marchant got the job.

Without notice further than the above the men refrained from work this morning, and apparently are out on strike. In this connection I am advised that Mr. Marchant is not an employee of this company and that he has not worked for this company for a period of five years and that the sole reason for refusing to employ him is that in the opinion of Mr. Derbyshire, he is not a competent miner.

I beg to call your attention to the terms of the agreement under which our mines are now working and made between this company and other members of the Western Coal Operators' Association and our employees, represented by the United Mine Workers of America, District No. 18, made May 4th, 1907, and represent that the action taken by the men at Michel is entirely contrary to the above agreement, and ask that you take the steps necessary to enforce the carrying out of the agreements in question on the part of the employees of this company whom you represent.

I assure you that these agreements were made in good faith by this company, and that expecting on our part to

carry them out in absolute good faith, we must look to the United Mine Workers of America, District No. 18, as sole representatives of our employees and the people with whom the agreements under which we are working were made, to do the same.

We are at all times ready to consider as provided in the agreements mentioned any grievances of our employees.

Yours truly,
The Crow's Nest Pass Coal Company.
per J. D. Hurd, general manager.

The following circular was issued by James Douglas and Charles Garner of the Michel Union of the U. M. W. of A.: "The Crows' Nest Pass Coal Company issued notices requesting the miners at Michel to resume work at once stating that they are now as before, willing to settle any trouble in the same liberal manner as heretofore. What stupendous magnanimity! The present suspension is simply a climax of a pin-prick policy pursued by the Coal Company's officials. Human tolerance has a breaking point. The company's officials have during the financial crisis humiliated and degraded the miners almost beyond endurance. They have cheated and told lies in the transactions between themselves and the Local Grievance Committee. Just now they have deliberately insulted the organization by an act of discrimination of the vilest and most flagrant kind. . . . . We are told that under the Canadian Labor Law, that we are liable. We claim that it does not cover our case and if it did we will greak any law in the constitution that encroaches upon our liberties. What law shall state, what line of demarcation has been fixed to define where liberty ends and where slavery starts? If a man is to be called upon to give his name why not call upon him to furnish a certificate of good conduct from the minister with a guarantee of his being meek and humble.

The Coal Company would transplant Russian methods in Michel, they will be successful when the men are starved out. If this condition prevails much longer we will call upon our brothers at Coal Creek and Fernie to take action in sympathy with us. We believe, however, that when General Manager Hurd is made cognisant of the true state of affairs this matter will be settled satisfactorily to both parties.

(Signed) Jas. Douglas, President.
Chas. Garner, Secretary.

Michel Local Union, No. 2234.

The following circular has been issued by the Union officials for the district:

To the members of Michel Local Union, U. M. W. of A. greetings.

A circular having been issued by Jas. Douglas and Chas. Garner of Michel Local, setting forth their position we deem it advisable to state the position of the District Union upon the dispute at Michel.

The action of the men at Michel in suspending work without first giving the District officers an opportunity of endeavoring to settle the matter as provided by the International constitution of the U. M. W. of A., is a wilful violation of the constitution also a breach of their agreement with the Crows' Nest Pass Coal Company. On behalf of the U. M. W. of A., we request the men to resume work and observe that the matter in dispute be handed the District officers for settlement. We have always been ready to take up any matters in dispute at Michel when properly placed in our hands and are so to-day. We have been denied that opportunity at Michel.

We again call upon loyal members of our organization at Michel to resume work and place their disputes in our hands.

Yours fraternally,
F. H. Sherman, President.
J. A. McDonald, Secretary.

The Michel mines produce about 2,000 tons of coal per day and as most of the coal is used for coking any stoppage at the mines lays a lot of men off work.

After the above circular had been issued by President Sherman, the men returned to work, but again went on strike, owing to twelve men having been discharged. The company claim they were discharged because they were off for two days without permission which is in accordance with Article No. 10 of the agreement.

A mass meeting was called at Fernie in the Opera House, where the miners, acting on the advice of President Sherman, passed an unanimous resolution advising the Michel men to again resume work and place the matter in the hands of the district officials and stating that if the Michel men could not then get justice, they would be supported by the treasury of the Fernie members. The Michel men called another meeting and decided to abide by the advice given.

Rossland.

The ore shipments from Rossland for the week ending May 23rd amounted to 4467 tons, including a 35 ton shipment from Giant-California. The industry is in a healthy condition in this district and the mines are all looking well. The gross output of the Le Roi for April was valued at $90,000 and the mine has much good ore in sight at the present time. Work at the Centre Star mines is proceeding along regular lines, their shipments running from 2,700 to 3,000 tons per week. Ore is being taken from the Danby Fraction, controlled by the Spitzee Company, and the St. Elmo has also bee nleased. There is some fairly good ore opened up in the St. Elmo, which is situated some 600 feet above Rossland on the side of Red Mountain. Development work continues to be done on the Curlew and in the course of the work they are taking out some good silver-lead ore.

Rossland has been favored by a visit from Dr. J. Bonsall Porter and Dr. J. A. Dresser, of McGill University, who have visited the camp with 35 of the McGill students.

The Le Roi No. 2, Limited, have located an ore body seven feet wide at a point 337 feet below their workings on the 900-foot level. This ore was located by means of diamond drill and carries 19 dwts. gold and 4.5 per cent. copper. It will be noted that this is a higher grade ore than generally found in either of the the other two big mines. This discovery is of more than passing interest to the Le Roi No. 2 Company, as it tends to prove the presence of ore in their property at depth and with two big mines like the Le Roi and the Centre Star adjoining their claims and with plenty of ore at depth it would appear to even a layman that the Le Roi No. 2 will have lots of ore to mine for a long time to come. Ore bodies in the Josie have so far run narrow but there is no good reason why wide bodies of ore should not be opened up at more depth.

W. Y. Williams, consulting engineer for Granby, came up from Spokane to look over the California-Giant work during the week. The White Bear Company is to be reorganized and an assessment levied with which work will be resumed. Some of the shareholders may not feel altogether in harmony with another assessment but now that the mine is almost in a position where it can pay its own way and with all of the other deep mines of the camp making good discoveries of ore it would be a pity to let the proposition go by the board when a small assessment might put it on the upward path.

The receipts at the Trail smelter are running over 4,000 tons per week, including ore from the Rambler-Cariboo, St. Eugene, Snowstorm, Richmond Eureka, First Thought, Crescent and Vancouver.

A meeting of the Mugwump and Monita Mining Companies is to be held in Rossland on June 23rd, for the purpose of winding up the affairs of these companies.

Phoenix.

Ore shipments to the British Columbia Copper Company's smelter were begun on the 18th of May and during the succeeding week 2,000 tons were shipped from the company's mines; 480 tons being shipped from the Denoro property. Things are getting in good running shape in the mines with the exception of a little shortage of first-class machine miners, while common labor is plentiful this class of mine help seems to be scarce, many of the best miners having left the Boundary during the recent shut-down and some of them have moved their families to other camps. Mr. E. G. Warren of the Greenwood Electric Company has been made general foreman of the Copper Company smelter. Mr. Warren is a good man and will no doubt handle his portion of the work in a satisfactory manner.

During the week ending May 30th, the ore shipments from the Boundary mines were: Granby 21,498, Mother Lode 3,510, and Oro Denoro 1,480 tons, making the total shipments from the district for the year to date 452,437 tons. The Granby smelter during the week treated 16,256 tons.

At the Granby smelter the wooden building covering the blowing engines is being replaced by a structure of steel and brick. The ore bins at the Gold Drop, which were on Snowshoe property have been removed and rebuilt at the Curlew. The remaining six furnaces will be connected up to the new flue dust chamber as quickly as possible, but the work will no doubt take two or three months yet.

The tunnel on the E. P. U. which is being worked by local people, has cut through some high grade gold and silver stringers, which would seem to indicate the approach to the lead. A strike of good ore has been made on the Buttercup in Wellington camp. The O. K. in Wellington camp and the Redona in Brown's camp have changed hands.

The McGill students have paid visits to the Phoenix and Greenwood mines during the week being shown all the points of interest. The work of making a geological survey of Phoenix camp is now in progress. This work will prove of invaluable assistance to the mining men of Phoenix.

An official announcement has at last been made that the Dominion Copper Company will start up its plant on June 15. One hundred men will be employed at the smelter and about two hundred at the mines. As the company has retained its staff of officials and there is plenty of coke, etc., on hand, it will not take very long to get things running. The financial condition of the company has been improved, which will greatly aid the local management in its efforts toward greater economy. It did not seem reasonable that the Dominion Company would find it advisable or profitable to remain idle with the other two big Boundary producers running full blast. There is no doubt but that the Dominion Copper Company will be in a position in the near future to produce copper at a much lower figure than they did during their last fiscal year while operating. They can do it if the other big mines and smelters can and no doubt some future report will show this an accomplished fact.

A new company is to be formed in Phoenix to operate the Woodburn and Woodburn fractional claims in Wellington camp. The claims have a good showing of copper-gold ore and have good railway facilities. They are regarded by local men as very promising properties. Work on the Stemwinder in Fairview camp has about ceased and the miners are leaving the camp.

The Tip Top mine in Skylark camp has moved its plant to a new location on its property and will do some work on the copper showing they have on the property.

It is stated by the promoters that all arrangements have been completed with the Phoenix-Greenwood tunnel proposition excepting the bonusing of the project by the city of Greenwood. As there are obstacles in the way of this some delay may be incurred.

The news has been received in the Boundary district with some relief that the strike of the coal miners of Michel had been settled. It was feared for a time that a parallel to the strike situation of last year was about to occur. As it was one or two furnaces had to be blown out owing to a small shortage of coke.

Nelson.

The hopes of the Nelson mining interests are once more turned toward the Silver King mine on the hill above the city, where Mr. M. S. Davys, an enterprising local mining man is working the mine under lease from the foreign interests which control it. The proposition looks promising but some little development work is necessary to demonstrate the presence and permanency of the lead in the lower levels.

It is expected that the Krao will resume work early in June. Now that the Queen mine has been taken over by Minneapolis interests a strong effort will be made to interest outside capital in the Sheep Creek district. There are a large number of promising prospects in this district and twenty cars of ore shipped from there to Trail smelter during the season have averaged around $100 per ton. Shipments from the Standard will be resumed as soon as the roads are in better conditon for hauling. About400 tons are on hand to be sent to Trail smelter as soon as it is possible to ship. On the Surprise work has been resumed on the crosscut which is already 2,500 feet. The news that zinc ore may be shipped to the United States duty free was received by the zinc miners of the Slocan with much gratification. This decision will not materially affect the Nelson Zinc smelter as it will no doubt get its full quota of ore from the nearby mines. The Whitewater mine has made a trial shipment of zinc ore to a Kansas smelter. The Fisher Maiden, in Slocan, which has not been worked for some time is to start work again in the near future. A majority of the stock in this company is held by Spokane interests.

GENERAL MINING NEWS

NOVA SCOTIA.

Halifax.—The agitation in the ranks of the Provincial Workmen's Association for affiliation with the U. MM. W. is to be settled by a referendum vote to be taken on June 24th. The various lodges will appoint their own returning officers and Mayor Douglas of Glace Bay will act as general returning officer for the whole province.

Sydney.—The two coal areas at Little Bras d'Or controlled by G. A. Forbes, of Montreal, and adjoining the territory of the Nova Scotia Coal Company, have passed into the hands of R. S. Cottrell, of Sydney, and W. A. Mackay, of North Sydney.

Halifax.—The invitation extended by the Mining Society of Nova Scotia to the Canadian Mining Institute to visit Sydney next August has been accepted. The Institute members will be accompanied by British and European delegates.

Londonderry.—Work at the mines and smelter of the Londonderry Iron and Mining Company has not yet been resumed.

ONTARIO.

Cobalt.—On Thursday, May 20, a party, including Mr. A. A. Cole, mining engineerfor the T. & N. O., left Cobalt to visit the unsurveyed country south of Lorrain. The Kelly claim was

visited. It was found that but little work had been done on this claim beyond surface trenching and a few shallow test pits. The party also visited the location on the southwest bay, known as "66." This will probably prove to be the best town site.

Thorold.—The smelter of the Coniagas Reduction Company is now in operation. Six cars of Cobalt ore are at Thorold ready for treatment.

Sudbury.—The Crystal Gold mine, near Wahnapitae Lake, has been sold to a Toronto syndicate by P. Shannon of Pembroke. It is reported that mining will be started at once.

BRITISH COLUMBIA.

Rossland.—While loading holes in a slope on the 11 limit of the Centre Star mine, on May 25, Maurice Powers, an old miner and shift boss, was instantly killed by a premature explosion. Powers was using a new explosive called Mitchellite.

Nelson.—Premier McBride, who is also Minister of Mines, visited Nelson on May 23rd.

Phoenix.—Nearly six miles of diamond drilling has been done up to the first of May at the Granby mines, Phoenix. Probably no mine or group of mines in British Columbia has had so many bores made. The work goes steadily on by the Boyle Bros., the contractors, who have done it all for the Granby company for nearly four years. The following figures give exactly what has been accomplished by the Granby company in diamond drilling, the total up to May 1 being 29,117 lineal feet as follows: Previous to 1904, 4,150 feet; in 1904, 3,148 feet; in 1905, 8,419 feet; in 1906,, 9,417 feet; in 1907, 3,983 feet. As boring was stopped in November of last year, when all mining and smelting in the Boundary took a complete rest, the total for 1907 was not very large. Then, again, this sort of work having been recommenced only a few weeks ago, the figures for 1908 will not likely equal those of 1907. For years the company has done its diamond drilling entirely by contract, while the Dominion Copper Company and the British Columbia Copper Company had their own diamond drills and did the work themselves. The latter, however, has been doing more and more of this work by contract of late, having a contract now in progress at its rich Lone Star and Washington mines near Danville, Wash.

Victoria.—The steamer Tees brought from the west coast a sample shipment of ore from the Klaskino Gold Mining Company's inlet. The shipment included half a ton of ore from the shaft. It has been sent to Vancouver for a mill test.

Vancouver.—The Guggenheims have finally abandoned work in Cariboo, and have given up the proposition to purchase the Cariboo Consolidated Hydraulic Company. This decision was reached after a hundred thousand dollars had been spent carrying out the initial work for digging a series of ditches for securing a water supply. The Guggenheims also paid a similar amount to the contractors to be released from the contract to install a water system which in all was to cost half a million dollars. The principal shareholders in the original enterprise are Sir William Van Horne and R. B. Angus of Montreal, to whom the property has now reverted. Sir William Van Horne recently wired instructions to Mr. Hobson to go ahead with the season's work, and preparations are being made for a big clean-up.

Victoria.—Assayers certificates have been granted to W. W. Lindsay, Rosland, and to V. L. Vaughan-Williams, Victoria.

YUKON.

Dawson.—Reports of the discovery of gold and of a stampede come from Log Cabin Creek in the Forty-Mile district. Many applications for claims staked have been received by mail in Dawson. The creek is a tributary of Forty-Mile river, fifteen miles above the Yukon. No grants will be issued until more information has been received.

Dawson.—Reports from the dredging companies indicate that by May 16th all will be in readiness to start the dredges. It is estimated that a combined output of about one million dollars per month will be attained this season. The Lewes river dredge, on 6 below Bonanza, had got steam up on May 6th. The big dredge of the Bonanza Basin Company was thoroughly overhauled last autumn. Her equipment is now operated entirely by electrical power.

Three of the Yukon Gold Company's dredges, two on 104 and one on 96, Bonanza, were expected to be in operation on the 8th of May. They were merely waiting for power from the Twelve mile station and water had begun to run freely in the flume there. The power station itself has been repaired and the foundations strengthened. The station is at an elevation of 1,800 feet greater than that of Dawson. Nevertheless the season is several weeks in advance of this locality. The second dredge on 90 will be ready early in June; the Arlington dredge not until July. Those at the Hillside and at 37 below will be even later.

If Black Hill Creek shows up well this summer as a gold producer a change in the route of the overland route to Whitehorse will result.

MINING NEWS OF THE WORLD.

GERMANY.

Dr. Hermann Wedding, professor of metallurgy at the Berlin School of Mines, is dead. He was the author of numerous treatises on metallurgy and an honorary member and Bessemer gold medallist of the British Iron and Steel Institute.

RUSSIA.

The iron ore production of Russia for 1907 was larger than in any previous year. Exchanging the manganese ore exported from Poti, it amounted to 262,100,000 poods, as compared with 236,400,000 poods in 1906. The amount exported was 605,000 poods in 1907, as against 33,300,000 poods the previous year.

The proposed trust of the Southern Metallurgical Works, preliminary arrangements for which have been effected, embraces mine companies which among them control 88.84 per cent. of the southern and 45.04 per cent. of the total Russian metallurgical output.

SWEDEN.

Gold has recently been discovered in the reefs and sands of the Topdal and Toovisdal rivers near Christianssand. Prospecting over a large area has established the fact that the gold bearing sands extend over a considerable tract of country.

UNITED STATES.

The American Petroleum Company of Los Angeles, Cal., has bought 1,200 acres of oil land in Coalinga district, Fresno County, Cal., for $2,000,000.

Work has been resumed on the Neversweat and West Gray rock copper mines, Butte, Montana, which leaves only one big

mine in the district still closed. A large amount of exploration work is being done. The amalgamated properties have greatly reduced the cost of copper production, which is believed not to exceed 10 cents per pound throughout the district.

Numerous rich strikes of gold are reported in Nevada County, Cal., the most important being in the Idaho-Maryland, one of the oldest quartz mines in Grass Valley, where a phenomenally rich ore body has been found on the 500 foot level.

Ground has been broken at Coaldale, Penn., for the erection of the largest breaker in that district by the Lehigh Coal & Navigation Company. It will have a daily output of 4,000 tons.

GREAT BRITAIN.

Returns received by the British Iron Trade Association give the production of Bessemer steel ingots for 1907 as 1,859,259 tons as against 1,907,338 tons in 1906. Of last year's output 1,280,315 tons were made by the acid process, and 578,944 tons by the basic process. The production of Bessemer steel rails in 1907 was 532,576 tons, as compared with 854,740 in the previous year.

The United Collieries, Limited, of Glasgow, have closed down six pits in Lanarkshire, owing to the low price of coal, throwing 900 men out of work.

The Dowlais-Cardiff Company, of Abercynon, Wales, recently established a record by raising 2,747 tons of coal during the day shift from a depth of 700 feet.

MEXICO.

Between 30 and 40 British mining companies are operating in Mexico with a capital of upwards of £7,000,000. France has £1,200,000 invested in similar enterprises, while the American capital employed in Mexican mining amounts to £25,000,000.

Construction work on the E. H. Harriman smelter at Mazatlan will shortly be started on a contract requiring the smelter to be completed by June of next year. The amount of capital to be invested is about $3,000,000. The smelter will afford a market for many mining sections in the west of Mexico.

The Barrateros mine near Cosala, in Sinaloa, which is one of the oldest in Mexico, having been worked by the Spainiards 360 years ago, has been secured by Mr. George F. Beveridge, of Los Angeles, Cal.

The extent to which American mining machinery has been introduced into Mexico is indicated by the fact that at the Pinguico mine, Guanajuato, no fewer than 250 Westinghouse electric motors are in operation.

COMPANY NOTES.

THE CONSOLIDATED MINING & SMELTING COMPANY.

The fiscal year of Consolidated ends on the last day of this month, and the gross value of its output will be in advance of the previous year. The first nine months' output exceeded the total yield for the entire previous fiscal year by about one hundred thousand dollars.

The production of the company for the quarter ending September 30, 1907, the half year ending December 31, and the nine months' period ending March 31, 1908, shows as follows in detail:—

Quarter ending September 30, 1907:

Metal produced.	Quantity.	G. value.	P.C.
Gold, ozs..	25,120	$514,960	38.85
Silver, oz..	522,719	287,925	21.73
Copper, lbs..	1,201,426	209,365	15.79
Lead, lbs....	7,205,567	313,142	23.63
Total		$1,325,392	100.00

Six months ending December 31, 1907:

Gold, ozs..	54,840	$1,124,219	39.40
Silver, ozs..	1,271,087	771,500	27.10
Copper, lbs..	2,348,359	353,308	12.40
Lead, lbs..	15,482,797	599,772	21.10
Total		$2,848,799	100.00

Nine months ending March 31, 1908:

Gold, ozs.....	90,306	$1,851,272	44.30
Silver, ozs..	1,761,431	1,042,847	24.95
Copper, lbs..	3,137,749	457,608	10.25
Lead, lbs..	22,807,389	827,059	19.80
Total		$4,178,786	100.00

The most interesting feature in these figures is the gradual rise in the percentage in value of gold produced to 44.30 per cent., which is accounted for by the larger and richer ore bodies being encountered in the low levels of the War Eagle and Centre Star. This increase in production of gold should be a most potent factor in adding steadiness to the earning power of the company.

At the annual meeting of the Silver Leaf Mining Company, held June 2nd, a statement was submitted showing that the organization and operating expenses for the year ended April 30th were $59,040.95, while the net profits for the period were $76,933.79.

The electors elected were: A. G. Browning, North Bay; Jno. L. Coffee, S. Cft Smoke, D. M. Robertson, C. W. Irwin, J. B. Chapin, Toronto; George L. Walker, Boston; J. L. Stanton, New York, and H. D. Symmons, Niagara Falls.

At a subsequent meeting of directors the following officers were elected for ensuing year: A. G. Browning, president; J. B. Chapin, vice-president; O. E. Osler, Thomas D. F. Maguire, secretary.

ABSTRACT OF FOSTER CIRCULAR.

Mr. John G. Kent, president of the Foster Cobalt Mining Company, has issued the following circular to shareholders:

It is just one year ago that the present board of the company assumed office, and one the 28th day of June, 1907, they called a special meeting of the shareholders to consider the condition of the property and to authorize certain development work, and also to authorize the sale of the treasury stock of the company. At that time the company showed an indebtedness, approximately, of $30,000, with 100,000 shares of stock in the treasury. There was also presented to the shareholders a statement of the physical condition of the property, prepared after inspection by Mr. Frank C. Loring, mining engineer.

During the past twelve months the property has been developed along the lines indicated in Mr. Loring's report, with the result that not only has this development been provided for, necessary buildings erected and appliances purchased, but there remains a substantial cash surplus sufficiently large to continue aggressive development for at least another twelve months.

In common with all mining experiences, the year's work has not been without the usual disappointments. Some ore bodies running high in silver, months ago, have not maintained their high silver value with the continuity which was hoped for, but, as will be seen by extracts from Mr. Loring's present report, there is every reason to expect a recurrence of high values at present and lower levels.

The treasury stock remaining on hand, unsold, is 84,412 shares.

Feeling assured that the shareholders of the company would be glad of information at this time, your directors again commissioned Mr. Loring to make a report of the property, and the following are extracts from this report:

"Vein No. 5—Between levels 1 and 2 there are probably 600 tons of ore, carrying more than ten per cent. cobalt per ton. So far as development shows, this ore is low in silver, not more than 40 ounces. Possibly, however, at any point between these two levels, rich silver ore may be encountered.

"On vein No. 8, an underhand stope is being mined from first level downward. From this stope the same rich ore which was mined above this level is being taken out. As to the depth this rich ore will continue, it is impossible to say.

"On vein No. 1, second level, should the copper sulphide ore there exposed continue to any great extent, it could be profitably mined for the copper contained, and the silver contained therein.

"On vein No. 1, at surface near lake, ore may continue down for some distance, and several carloads may be extracted therefrom. It is, however, impossible to predict what quantity of high grade ore can be expected.

"Therefore, so far as ore that can at present be marketed profitably is concerned, ore reserves consist of:

"Ore high in cobalt, low in silver, on vein No. 5 between levels 1 and 2;

"Ore high in cobalt, low in silver, on vein No. 8 above second level;

"Ore rich in silver, having a present length of about 30 feet below first level, vein No. 8;

"On vein No. 1, at surface, ore extending southeasterly from lake for a distance of about 80 feet, and probably extending into lake. The depth and extent of this ore body is unknown, but may yield a considerable quantity of high grade ore.

"All development work, timbering and buildings, have been done and constructed in a substantial and miner-like manner, giving evidence of skill and intelligence in operation, and for the best interest of the shareholders.

"Development work, especially on veins Nos. 1, 5 and 8, gives additional proof that these veins are strong and will continue to great depth, and there is more reason than there has ever been before for continuing development to far greater depth, with a strong probability that ore bodies high in silver will be encountered at some point. I, therefore, recommend vigorous and extensive additional exploration in depth, especially on veins 1, 5 and 8.

"It should be borne in mind, however, that this work is necessarily expensive, consequently ample provision should be made by maintaining large cash reserves, that any possible contingency or delay in the encountering of rich ore bodies may be provided for.

"(Sgd.) FRANK C. LORING,
"Mining Engineer."

"Toronto, Ont., May 29, 1908."

Your directors feel that they have every reason to proceed with the development of the property along the well-defined lines already followed, and while still refraining from making definite predictions as to the values to be recovered, they have every reason to feel the greatest encouragement from results already obtained, and that the prospects are very favorable.

Reports which are absolutely untrue have been circulated in some quarters regarding the mine. Your directors cannot meet such incorrect statements every time they are made, nor can directors of any mine be expected to reply to all the misleading paragraphs which appear from time to time regarding most of the Cobalt properties.

The facts concerning "Foster" are given above, and it is hoped that the shareholders will feel, as the fact is, that the above report is not only true, but conservative in every respect.

Shareholders are invited to inspect maps and details of workings on file at the head office of the company.

The directors of the Dominion Coal Company met in Montreal on May 27th and declared the regular quarterly dividend of 1 per cent. on the common stock, payable July 1st.

On June 2nd the directors of the Granby Consolidated Company decided to resume dividends, and declared 2 per cent., payable June 30, to stockholders of record of June 12.

The Granby Company during 1906 paid quarterly dividends of 2 per cent. and 1 per cent. extra in January, May, September and December, and in 1907 in March, June and September.

Dividends stopped then, for the bottom dropped out of the copper market. This is the way Granby stock fluctuated during 1907:

	High.	Low.
January	140	130
February	151	130
March	146	120
April	136	125
May	139	125¼
June	125½	117½
July	127¼	121
August	115	99
September	100	80
October	92	60
November	90	70
December	80	70

The directors did not make a statement, but it is presumed that the stock is now on an 8 per cent. basis.

STATISTICS AND RETURNS.

The Transvaal gold output in May, as estimated by Kaffir houses in London, was 580,00 ounces, fine. The April output was 565,832 fine ounces; that of May last year 524,477.

If it proves correct, says The Post, this May estimate of the Rand will match all records. The total of last December was 583,526 ounces, but included a large amount "taken from reserves." Value of the May output calculated on the basis of the above estimate, compares as follows:—May, 1908, $12,325,000; April, 1908, $11,924,000; March, 1908, $12,210,000; February, 1908, $11,510,000; January, 1908, $11,900,000; December, 1907, $12,393,000; May, 1907, $11,139,000; May, 1906, $9,795,000; May, 1905, $8,843,000; May, 1904, $6,679,000; May, 1903, $4,973,000; May, 1902, $2,943,000.

Shipments from the collieries of the Cumberland Railway & Coal Company for the month of May were 24,710 tons.

For the month of May the output of coal from the four collieries of the Nova Scotia Steel & Coal Company was about the same as the preceding month. The output from No. 4 is gradually increasing, having almost doubled the output of April. Following are the figures from the different collieries:

	Tons.
No. 1	21,298
No. 2	23,784
No. 4	1,116
No. 5	7,390
Total	53,588

The output of pig iron at the blast furnaces was the largest since the company's existence, 6,064 tons.

May was a busy month at the Dominion Steel Works, and the output exceeded the big figures of Apral. The May output was as follows:

Pig iron	21,864
Ingots	5,650
Blooms	20,045
Rails	12,316
Rods	3,765

Dominion Coal's May output was 332,588 tons, against 327,269 tons last year.

This makes the company's output 242,899 tons ahead of a year ago for the five months:

	1908 Tons.	1907 Tons.
January	314,108	252,248
February	285,649	225,988
March	346,529	212,831
April	298,745	316,384
May	332,588	327,269
Total	$1,577,619	$1,334,720

Following are the weekly shipments from Cobalt camp, and those from Jan. 1 to date:

	Week end May 30.	Since Jan. 1
Coniagas	62,030	505,580
Drummond	56,260	148,600
La Rose	60,000	2,181,652
McKinley	66,540	1,373,560
Nipissing	184,220	1,548,110
O'Brien	254,810	2,357,130
Silver Queen	110,310	634,510
Trethewey	124,850	997,456

The total shipments for the week were 919,020 pounds, or 459 tons.

Cobalt ore shipments for the week ending May 25th totalled 905,780 pounds, or 452 tons.

The total shipments for the year to date are 13,210,228 pounds, or 6,605 tons. The shipments by mine follow in pounds:

	Week ended May 25	From Jan. 1
Buffalo	451,000	510,810
Coniagas	62,640	444,550
La Rose	140,000	2,121,652
McKinley	63,120	1,307,020
O'Brien	275,450	1,106,220
Right of Way	61,060	242,240
Silver Leaf	63,820	196,620
Trethewey	192,690	872,606

Following are the weekly shipments from Cobalt camp, and those from Jan. 1 to date:

	Week end June 6	Since Jan. 1
Buffalo	42,900	653,710
Coniagas	.....	505,580
Cobalt Lake	.....	246,455
Crown Reserve	44,000	84,000
Cobalt Central	.....	56,380
City of Cobalt	113,510	452,110
Drummond	.....	148,000
Foster	.....	238,400
Kerr Lake	101,650	404,320
King Edward	.....	127,240
La Rose	120,000	2,301,652
McKinley	.....	1,373,560
Nipissing	.....	1,746,120
Nova Scotia	.....	227,555
Nancy Helen	.....	140,420
O'Brien	183,840	2,540,970
Right of Way	.....	242,240
Provincial	.....	143,210
Standard	.....	39,730
Silver Leaf	.....	196,620
Silver Cliff	.....	52,000
Silver Queen	.....	634,510
Townsite	.....	85,100
Temiskaming & H. B.	.....	599,000
Temiskaming	.....	325,390
Trethewey	.....	997,456
Watts	65,590	246,020

The total shipments for the week were 866,500 pounds, or 433 tons. The total shipments from Jan. 1 to date are 14,995,748 pounds, or 7497 tons.

The folowing are the shipments from the various mines in the districts of Southeastern British Columbia and the receipts at smelters for the past week, ending May 23rd and year to date:

Ore Shipments:

Mine.	Week.	Year.
Boundary—		
Granby	20,766	522,760
Mother Lode	2,000	2,000
Oro Denoro	480	480
Crescent	30	58
Other mines	...	434
Total	23,276	425,732
Rossland		
Centre Star	2,647	68,380
Le Roi	1,580	31,538
Le Roi No. 2	316	12,320
Other mines	...	500
Slocan Kootenay—		
Whitewater (milled)	280	5,740
Poorman (milled)	250	4,380
Queen (milled)	185	3,690
Second Relief (milled)	145	2,100
St. Eugene	81	8,720
Richmond	76	681
Rambler-Cariboo	42	587
Vancouver	20	521
Other mines	...	15,077
Total	1,079	41,496

Smelter Receipts—		
Granby	20,766	422,720
Greenwood	2,480	2,480
Trail	4,088	109,205
Northport (Le Roi)	1,740	33,693
Marysville	....	5,730
Total	29,074	573,828

The following are the ore shipments for the past week, ending May 30th, and year to date, from the mines of Southeastern British Columbia, and the receipts at the smelters of the district:

Rossland, B.C., June 6.—Following are the shipments from the Rossland mines for the week ending this evening:—Centre Star, 3,860 tons; Le Roi, 1,610 tons; Le Roi No. 2, 385 tons. Total for the week, 5,855 tons, and for the year, 126,892 tons.

The output of the Crow's Nest Pass collieries for the week ending June 5th was 20,899 tons, or a daily average of 3,483 tons. Same week last year, 21,696 tons; daily average, 3,616 tons. Same week, 1906, 20,523 tons.

month of April amounted to 19,948 tons, being a decrease of 598 tons, as compared with the corresponding month last year; while the total output, from July 1 last, amounts to 225,000 tons, an increase of 12,528 tons.

The output of coal from the Crow's Nest Pass collieries for the week ending May 29th was 10,212 tons; daily average, 1,702 tons; same week, 1907, 21,504 tons; daily average, 3,584 tons; same week, 1906, 20,835 tons.

MARKET REPORTS.

Coke.

June 5—Connellsville coke, f.o.b. ovens—
Furnace coke, prompt, $1.5 to $1.60.
Foundry coke, prompt, $2.00 to $2.25.

Pig Iron.

June 5—Pittsburg—
No. 2 foundry, $15.40 to $15.90.
Bessemer, $16.90 to $17.15.
Basic, $16.15 to $16.40.
Malleable, $15.90 to $16.40.
Southern No. 2, $15.15 to $15.40.

Other Metals.

June 5—
Tin, Straits, 28.35 cents.
Copper, prime lake, 12.87½ to 13 cents.
Lake arsenical brands, 12.85 cents.
Electrolytic copper, 12.85 cents.
Sheet copper, 17 cents.
Copper wire, 14.75 cents.
Lead, 4.40 cents.
Spelter, 4.67½ cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.70 cents.
Aluminium, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $22.50 to $25 per ounce.
Bismuth, $1.75 per pound.
Quicksilver, $45 per 75 pound flask.

June 5	52 7/8	24 3/8
June 6	52 7/8	24 3/8

MARKET NOTES.

A cut of $4 a ton in bar steel went into effect on June 3rd in Cleveland. The new price goes into effect at once, but will effect only manufacturers' stock. The cut is based upon the Pittsburg rate of $1.60 per hundred pounds. The new price is $1.40 per hundred. This reduction will probably induce a better coke trade.

A considerable quantity of lead is held in stock. It is therefore hard to judge the actual position of the metal. It is doubtful if the price would hold if the reserves were placed on the market.

The small stocks of copper in the hands of manufacturers should result in higher prices in the near future. Demand is still lower than normal.

Machinery for Sale at a Bargain

1 Corlis Engine, 16" x 36", with separate condenser. In good condition. Completely overhauled six months ago.

1 Internally Fired Scotch Boiler, about 86" dia. x 18' 0" long. Two furnaces, 33" dia. x 6' 0" long. 136 tubes, 10' 0" long, 3" dia., about 200 H.P.

2 30 K.W., 110-v. D.C. Generators, 800 r.p.m., multipolar, compound wound, complete with pulleys. In excellent condition.

1 60 K.W., 250-v. D.C. Generator, 700 r.p.m., 6-pole compound wound. This machine is also in first-class condition.

1 Duplex Pump (Worthington), 9" x 5¼" x 10". In good condition.

1 Pump (Union Steam Pump Co.), steam cylinder, 5 1/8" dia., 3 5/8" stroke. Pump cylinder 8" dia.

2 Six-ton, 19-ft. Jib Cranes (steel frame). In good condition.

1 5-ton, 17-ft. Jib Crane (steel frame), in good condition.

1 Portable Key-way Slotter (Morton Mfg. Co.). In first-class condition, scarcely used.
Also some lathes, shapers, &c.

All the above have been in use until recently and can be put into service immediately. They will be sold either singly or "en bloc." Apply to THE CANADIAN LOCOMOTIVE COMPANY, LIMITED, KINGSTON, ONT.

Amatite ROOFING

THIS advertisement will bring to your attention the *best and cheapest ready roofing* on the market. Here is how we prove it the best.

In the first place Amatite is made in one standard thickness, whereas other ready roofings range from a thin, flimsy half-ply to a three-ply thickness.

The three-ply thickness (which by the way is only one sheet of felt) is the only kind that can be compared with Amatite.

But right here is the point. Amatite is better made, has better water-proofing material, and weighs more per square foot than the three-ply grade of other makes, and *costs much less.*

These facts make Amatite the most desirable roofing made.

But in addition to its superiority in material and manufacture, Amatite has one distinction which makes it stand out above all others. *It has a real mineral surface.*

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather, the great durability.

This mineral surface is embedded in a layer of Pitch, *the greatest known waterproofing material.* Beneath this in turn are two layers of the best grade of wool felt—cemented together by more Pitch, making the whole a roofing that is *absolutely waterproof.*

No other ready roofing can compare with this mineral-surfaced, water-proof, weather-proof, durable roof. That's why we say—*Don't buy your roofing until you have seen Amatite.*

FREE SAMPLE AND BOOKLET

POSITION WANTED BY MINING ENGINEER

Twenty years' practical experience on Lake Superior, also among the complex ore mines of the West, filling positions from clerk to general manager. Can show remarkable record for reduction of costs, etc. Highest indorsements. Can go anywhere. Will accept any reasonable offer. Age 40; married; strictly temperate. Address, H. F. E., c/o CANADIAN MINING JOURNAL.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLAR

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

Machinery for Sale

Four INGERSOLL-SERGEANT Class "A" Straight Line Air Compressors. Air Cylinders 26¼ ins. x 30 ins. In good working condition. Available about July, 1908.

One VULCAN, four-wheel, Saddle tank, Steam Locomotive, 42 ins. gauge. Cylinders 10½ ins. x 16 ins. Built 1903. Immediate delivery.

One CANADIAN, four-wheel, Saddle tank Steam Locomotive, 42 ins. gauge, Cylinders 10 ins. x 14 ins. Built 1902. Immediate delivery.

One PORTER, four-wheel, Saddle tank, Steam Locomotive, Standard Gauge 4 ft. and ½ in. Cylinders 7 ins. x 12 ins. Purchased 1901. Immediate delivery.

Four JEFFREY, ten ton, Electric Locomotives, 36 ins. gauge, 220 volt. Direct Current. In good working order. Available about July, 1908.

Three LIDGERWOOD ELECTRIC HOISTS, 75 H.P. Equipped with duplicate Jeffrey M. H. 30 H.P. Motors' 220 volt. Direct Current. Available about May, 1908.

One ALDRICH ELECTRIC PUMP. Portable, mounted for 16 ins. track. Capacity 100 gallons on 300 ft. lift. Equipped with 10 H.P. Westinghouse Motor, 220 volt. Direct Current. Purchased 1907. Immediate delivery.

The Machinery listed above will all be available during the present season, owing to being replaced by larger equipment.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

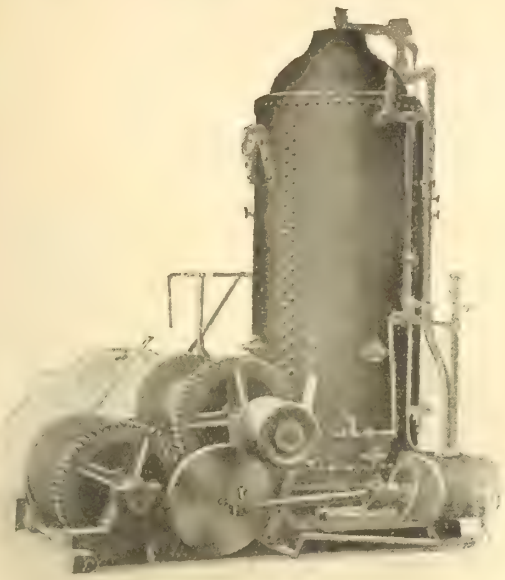
RAND AIR COMPRESSORS

EFFICIENT AND ECONOMICAL



Complicated mechanism in air compressor design is regarded as an element of weakness and it is the elimination of such non-essentials that has produced the up-to-date RAND Machine; a machine which operates with the minimum of attention and repairs.

Our Catalogs describe Rand Compressor Construction.

Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work by reason of their high air efficiency, substantial design and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)

SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines, in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.

Gold Medal—Coal and Coke—Lewis & Clark Exposition, 1905. Silver Medal—Coal and Coke—Paris Universal Exposition, 1900.

Mines and Coke Ovens at Fernie, Coal Creek, Michel and Carbonado.

Annual Capacity of Mines, 2,000,000 tons. Coke Ovens, 500,000 tons.

We are shipping domestic coal to points in Manitoba, Alberta, Saskatchewan, British Columbia, Montana, Washington and Idaho, a territory of over 400,000 square miles, and WE ARE GIVING SATISFACTION.

We are shipping steam coal from Winnipeg to the Pacific Coast, and not only is it used in that vast area by the Railways and the largest firms, but also by the Great Northern Steamship Company's liners plying between Seattle and the Orient.

Our Michel Blacksmith coal is used in Railway forging shops in Winnipeg, seven hundred miles East, and in Vancouver, four hundred miles West.

Ask a British Columbia smelter Superintendent what coke he uses, and what coke gives him best satisfaction.

Our Analyses Speak for Themselves.

R. G. DRINNEN, Superintendent. C. C. S. LINDSEY, General Manager.

OFF FOR THE COAST

"See Canada First"

Go yourself this summer, see with your own eyes the wonderland of Western Canada. Wide sweeps of prairie, following the timber country, and followed by the finest mountain scenery in the world, ranges of peaks thousands of feet high, all can be

seen at ease from the trains of the

CANADIAN PACIFIC RAILWAY

No more delightful vacation trip imaginable. Not an expensive trip, summer tourist rates and occasional excursion rates considerably reduce the cost.

Let us help you plan your tour, so you will miss nothing. It will be a pleasure to answer enquiries.

GLASS HOUSES.

An effort is being made in Mexico to push through legislation that will exclude foreigners from acquiring or retaining the ownership of Mexican mining properties. Our United States contemporaries are protesting vigorously against this drastic and short-sighted proposal. It is believed that President Diaz will not, under any circumstances, consent to the passage of such an unjust enactment.

The moment is opportune for the fervid Republic to our immediate south to do some soul-searching. Is it not so that in some of the States aliens are unable to locate or to acquire mining claims? Or, better, how does Mexico's treatment of the United States investor compare with the treatment accorded foreign investors in mining property in the United States? Is it possible that Mexico is not the only country that has considered enactments inimical to the interests of the stranger within her gate?

"On the question as to whether an alien can make a valid location," says a recognized United States authority, "there has been some conflict among the cases . . . An alien by making a location obtains rights in which he will be protected by the courts against all the world except the Government, which, as the owner of the land, has the sole right to dispute his possession . . . But this is true only so long as the alien allows his rights to rest in location; for he cannot obtain a patent because his citizenship, or declaration of intention to become such, must affirmatively appear before patent be granted . . . Some of the mining States have statutory provisions that the location certificate that is recorded must contain a sworn statement that the locator is a citizen or has declared his intention to become such."

In the light of these facts the situation is not devoid of humor.

CHAMBERS-FERLAND.

La Rose Consolidated was the subject of editorial comment in the last number of "The Canadian Mining Journal." The announcement of the Chambers-Ferland flotation is equally deserving of remark.

The Chambers Ferland property comprises 121 acres situated advantageously, even strikingly. Part of the property surrounds La Rose. South, east and west the O'Brien and Nipissing are immediate neighbors. Other facts lead to the conclusion that, to say the most, Chambers-Ferland is a property of high promise.

However, none but the most superficial development has been performed. Thus, to a considerable degree,

Chambers-Ferland's value is speculative. Incidentally the owners of this property exhibit the same curious, unmodern self-abnegation. They prefer not to work for their own gain a property that they assert will return enormous dividends. Quite seriously, it is hardly in keeping with previous experiences and fixed beliefs to encounter altruism of this high type. The property could have been leased long ago to operators as other Cobalt mines have been. It would now have been a proved property.

Apart from this element of mystery we see no reason why Chambers-Ferland, even with the drag of a 25 per cent. royalty, should not become a successful mine.

In estimating the possibilities of the enterprise, there are several factors that must not be overlooked. The share capital is $2,500,000. An adequate net profit for a year's operations would hardly be less than $500,000, of which $125,000 would go to the Provincial coffers as royalty. Building and equipment, especially if a concentrating mill is to be erected, prospecting, and surface work, will unquestionably draw largely upon the earnings of the first year or, rather, two years of operation. If the mine yields 15 per cent. per annum to shareholders it will not be doing more than should be expected. With a life of ten years this rate of regular dividend payment would be by no means other than modest. If, however, the shares (which, we are informed, will be offered to the public at 75 cents) are forced beyond parity (one dollar), there is no present foundation for considering them of exceptional value.

At this stage of the game opinions are merely—opinions. Whatever facts have been definitely ascertained should be looked at in all their bearings. The lack of development, the impossibility of making immediate heavy shipments, our ignorance as to how much of the Ferland-Chambers ore will prove high grade and how much will have to be concentrated, the absence of positive ore reserves, are considerations that should be weighed against the favorable aspects of the proposition.

Also there is a sharp distinction as between the *opinion* of a mining engineer as to the possibilities of an unprospected property, and the careful, accurate report upon the actual present physical condition of that property by the same man.

Opinions are merely expressions of personal belief. In a mining engineer's report they are of secondary importance. On the other hand, a report is essentially a record of facts and conditions from a man trained to observe and to correlate accurately. Hence, until reasons based upon observed facts are adduced in support of opinions, the opinion of a mining engineer, whether it be laudatory or damnatory, must be taken as having precisely the same amount of the speculative in it as there is in the mine itself.

We do not question the sincerity of expert opinions quoted or to be quoted. The fact remains, however, that there is much yet to be learned about Chambers-Ferland. And the only path to knowledge is vigorous and economical prospecting.

It may also be added that $2,500,000 is not a low capitalization for an undeveloped mining property.

MINING ENGINEERS IN POLITICS.

Canadian parliamentarians are drawn largely from the ranks of practising lawyers, prominent merchants, doctors, journalists, a sprinkling of farmers and labor representatives, and a miscellaneous residue, including an occasional preacher.

The profession of mining engineering has no direct representative. The industry of mining is attaining an importance that warrants the presence of at least a few mining engineers in our parliaments. Much-needed legislation would then receive fuller and saner discussion than is now possible.

The mining engineer, from the extent of his field and the nature of his work, acquires a knowledge of his country that can hadly be equalled. He would bring to his legislative duties all the qualities of good citizenship with the added special equipment necessary to the practice of an exacting profession.

SCRIBES AND SCRIBBLING.

For the edification of the down-trodden coal miner there are scribes a-plenty. The uplifting screeds of one or two of these excellent persons are the text on which our Nova Scotian correspondent hangs a forceful sermon.

An English writer, quoted in a Canadian newspaper, puts forward the extraordinary statement that from figures quoted "it will be clear that the miners wages are an almost negligible item in the cost of coal." Developing his theme he boldly asserts that if the "swollen profits" of parasites could be excised, coal could be sold at a much lower price.

A complete answer to this argument lies in the fact that in ordinary coal mining operations wages constitute from 70 per cent. to 80 per cent. of the working expenses.

We see little good and much harm in giving a hearing to agitators or others who are so scantily informed on the subjects of which they write. As our correspondent points out, the persistent clamour for class legislation in favor of coal miners is based upon a fundamental error. There is no essential merit in earning one's living by physical labor. Neither is there essential blame or shame. But there is blindness and foolishness in claiming that only the workingman who toils with his hands is deserving of special privileges.

SUDBURY AND TORONTO.

The new Canadian Pacific direct line from Toronto to Sudbury reduces the time of that journey by eight hours. Sudbury is thus brought substantially closer to the metropolis of Ontario. The handling of freight from and to an important mining and railway centre is the keynote of development. The new line will increase materially both freight and passenger traffic facilities.

We do not doubt that an impetus will be given to the opening up of the known copper deposits of the Sudbury region. Present freight rates are by no means at an irreducible minimum. In operation the direct route may reduce competitive reduction of tariffs.

Incidentally Sudbury will acquire added importance as a shipping and distributing point.

A NEW MARKET FOR BRITISH COLUMBIA COAL.

The establishment of a large coaling station on the Pacific coast of Mexico is announced. Manganillo harbor has been chosen as the site. If all goes well it is expected that the improved facilities to be provided at this port will encourage the exportation of British Columbia coal from the coast collieries.

It may be justly remarked that one of the first needs of Vancouver and Victoria and the coast generally is cheaper coal. The prices at which the fuel is sold in these cities are unnecessarily high.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

The Mines of the Glace Bay Basin.

(Article II. by F. W. Gray.)

The Glace Bay Basin has been much more extensively worked than any other portion of the Sydney coalfield, although as may be seen from an examination of the following comparative chart of outputs, it was the last of the basins to be systematically opened up. As will be seen from the chart the output curves of the four basins ran almost together during the first two decades of coal mining in Cape Breton, and it was not until the early 'eighties'' that the production of the Glace Bay Basin began to sensibly exceed that of the other sections of the Sydney coalfield.

From 1880 to 1893 the outputs increased steadily. In 1893 the Dominion Coal Company commenced operations, and from that time on the outputs have increased by leaps and bounds.

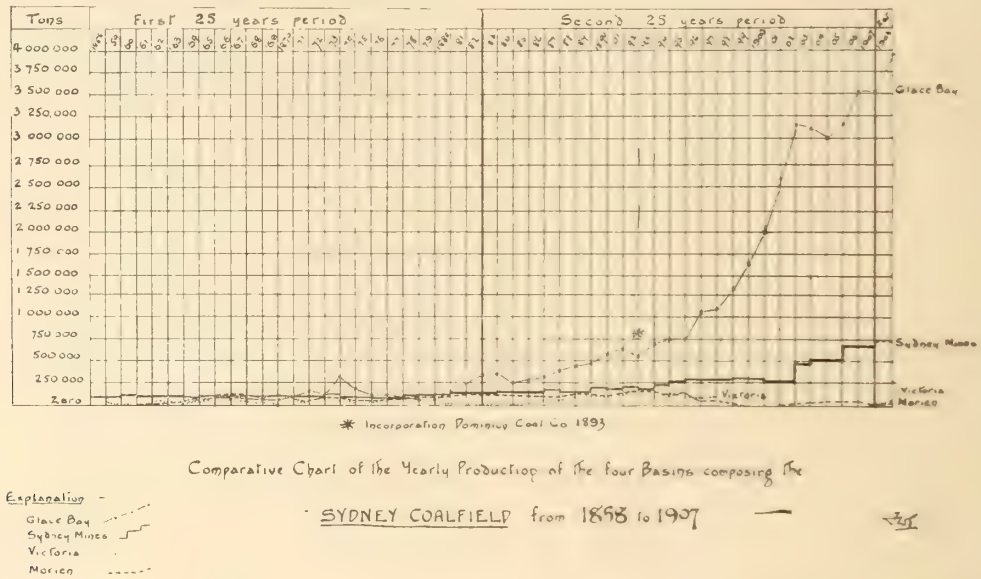
The following table gives the outputs of each basin of the Sidney coalfield from 1893 to 1907, arranged in two periods of twenty-five years, showing how remarkable has been the development of the coal mining industry during the quarter of a century just passed compared with that which immediately preceded it.

	Production from 1858 to 1882.	Production from 1883 to 1907.
Sydney Mines Basin	2,636,000	6,963,000
Lingan Victoria Basin	842,000	1,175,000
Morien Basin	1,779,000	1,850,000
Glace Bay	2,596,000	35,900,000
	7,853,000	45,888,000

During the fifteen years that have elapsed since the formation of the Dominion Coal Company, they have produced from their mines, in the Glace Bay Basin only, a little over 32,000,000 tons of coal, to which the various seams have contributed in approximately the following proportions:

		Per cent.
Gardiner seam	30,000	..
Emery seam	260,000	1
Hub seam	800,000	2½
Harbour seam	4,510,000	14
Phalen seam	26,400,000	82½
Total	32,000,000	100

The basin, or to use a more exact simile, the "saucer like" formation of this field is very marked, and the crops of the coal seams have been bared by the scour of the ice-age, so that, owing to the even flatness of the surface, and the regular pitch and consistent parallelism of the coal seams, they appear on the map in strikingly symmetrical concentric form.



There is a complete absence of faulting or dislocation of the strata in this field, although there are occasional undulations or "swillies," and local changes in the thickness of the seams, such as are to be met with in all coal deposits.

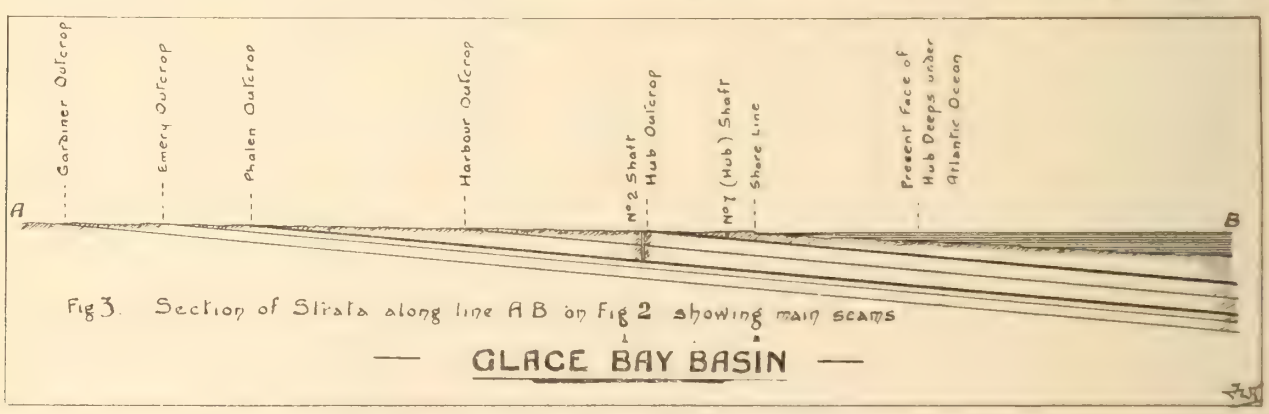
In the earlier days of coal mining in the Glace Bay district the seams apear to have been attacked from the outcrops in a happy-go-lucky and haphazard manner, without much regard for the future. No barriers, or very inadequate ones, were left along the crops to protect the lower and later workings, while the pillars left in the first operation were too small, the consequence being that much coal has been lost by creeps and crushes in addition to which the surface water has found its way through the many openings in the outcrops, leaving a legacy of pumping cost to the present generation. The measures in this district are "short" and brittle, and where the cover is light they will

break up today after the excavation of the underlying coal seams, thus admitting the surface drainage.

The land area of the Glace Bay field would have been a positively ideal one for easy and cheap working had it been mined to the rise from properly located shafts. Had this been done, haulage and pumping problems would have been simplified exceedingly, but instead most of the coal has been hauled from the deep.

The genesis of this short-sighted and expensive procedure is to be found in the fact that the coal field was

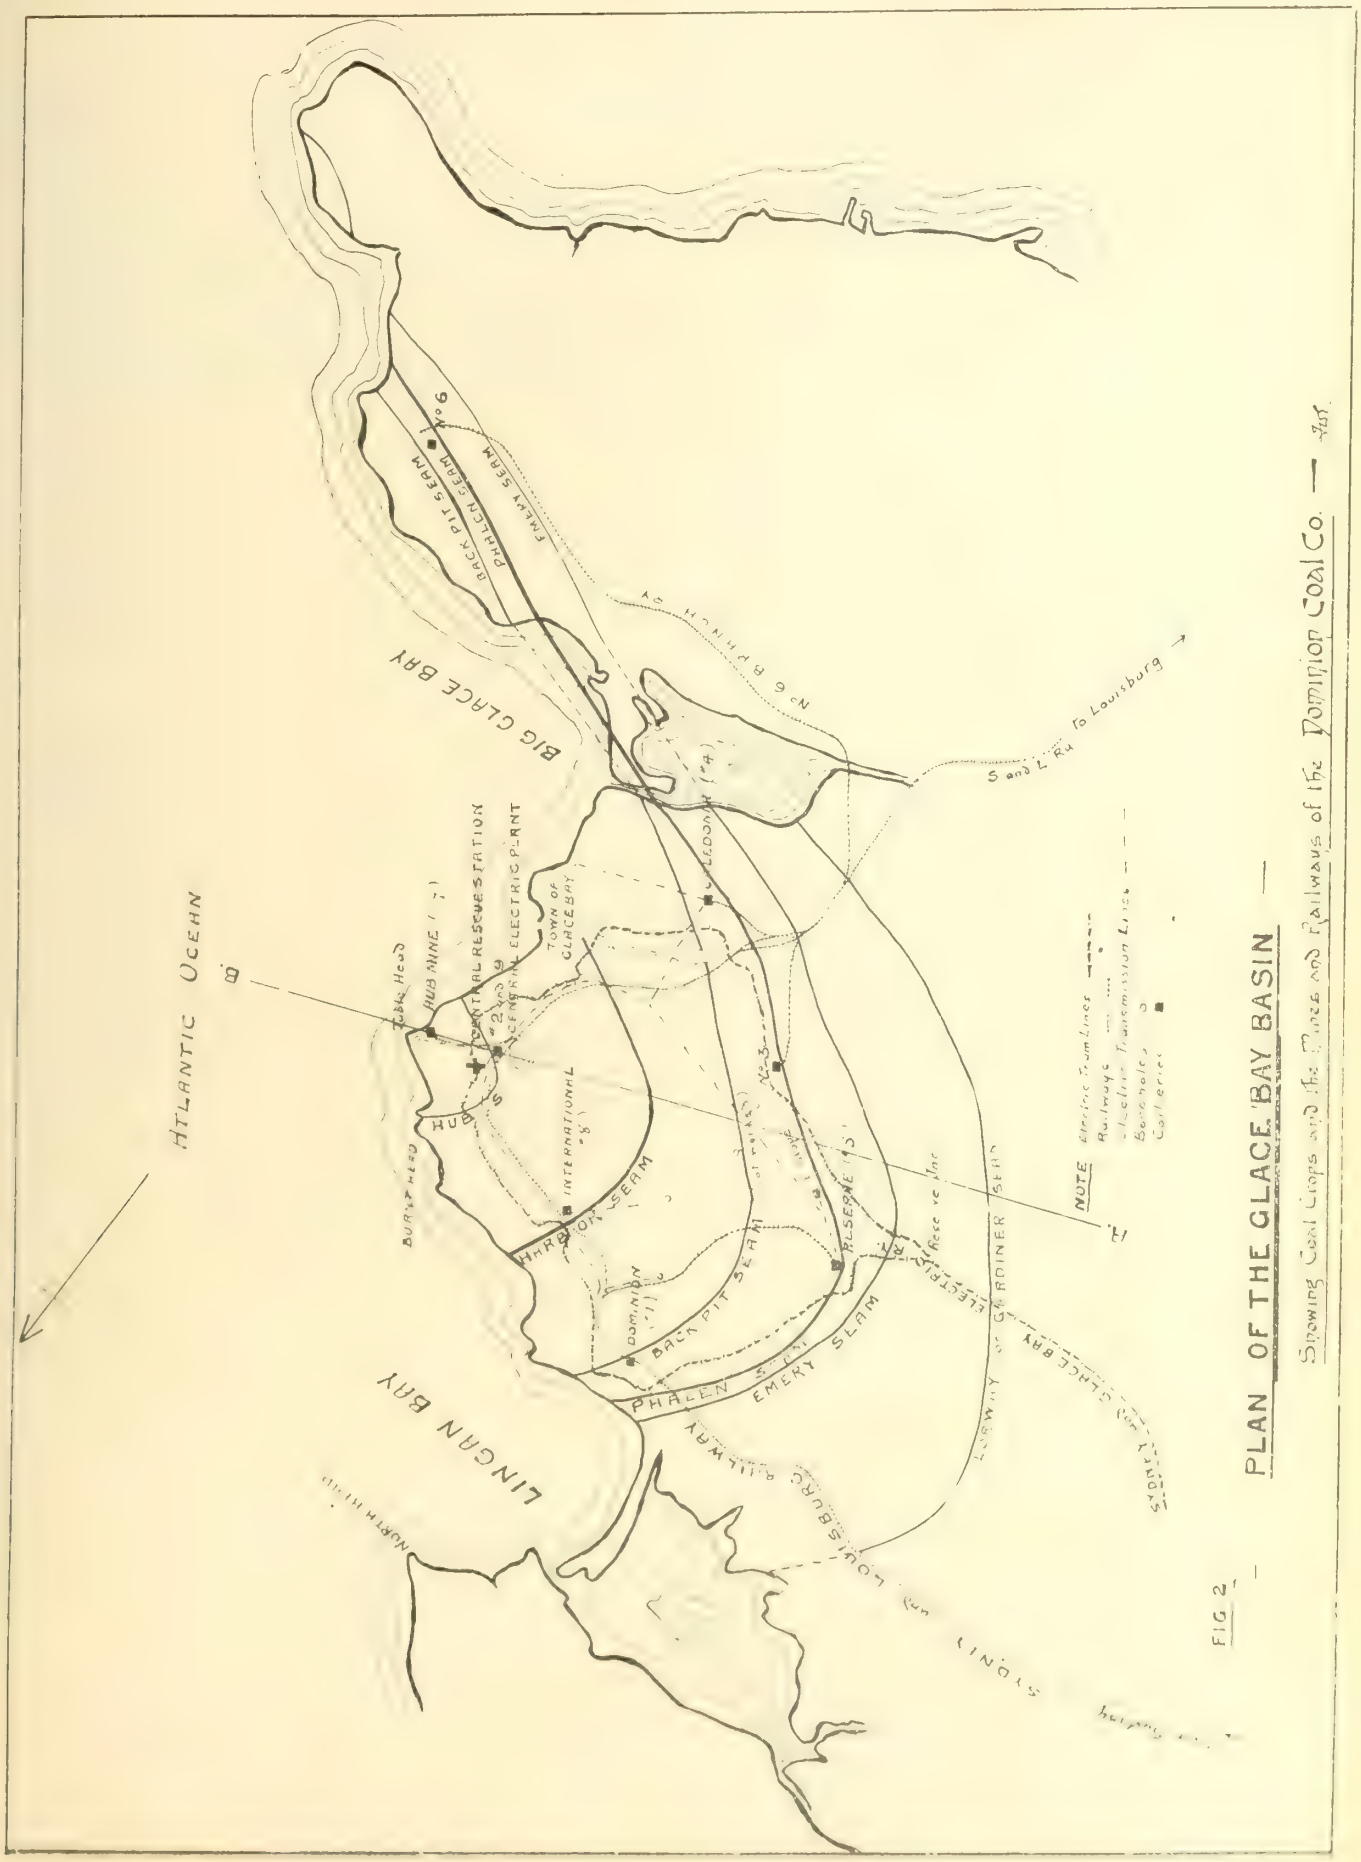
of the operator, the revenue of the Provincial Government, or the price of coal to the consumer. This statement is based on considerations of an engineering character only. Equally cogent and weighty commercial factors could be adduced in support of this statement, but such considerations are outside the scope of this description. When it is borne in mind that in 15 years the Dominion Coal Company produced more coal by 50 per cent. than was produced in the 35 years that that preceded their incorporation, it will be recog-



operated by independent and rival companies, with inadequate capital, who, to quote from a report made by H. Y. Hind in 1871, "allowed the desire for an immediate profit to supersede the necessity of a judicious arrangement of the mode of working."

It was therefore, very decidedly for the benefit of all concerned in the mining of coal in this district that a consolidation of interests should take place. This occurred when the Dominion Coal Company was formed, and there can be no doubt that had the Glace Bay Basin been worked as a virgin field by this or a similar corporation the result would have been a marked conservation of our national coal resources, and, incidentally, cheaper coal at the present time.

One could hardly conceive from an engineering or economic standpoint a series of mines where an amalgamation of interests was more desirable, or where independent operation was more likely to have disastrous future consequences, alike as regards the profits



nized what their operations have meant to the trade of the Dominion generally, and the prosperity of Cape Breton in particular.

Taking the coal seams in the order of their relative importance, the Phalen seam first claims attention. It is worked from six collieries, commencing with No. 1 ("Dominion") at the western limit, and ending with No. 6 on the eastern side. The land area bounded by Lingan Bay on the west and by Big Glace Bay on the

east, is worked by the first five mines. No. 2 mine occupies the centre of the basin, while Nos. 1, 5, 3 and 4 workings cover the rise coal, radiating from west to east in the order given, like the spokes of a wheel. The territory on the other side of Big Glace Bay Lake is worked from No. 6 mine. Nos. 3 and 5 mines have an all-land territory, while Nos. 1, 2, 4 and 6 have submarine territory in addition to their land areas.

It is not necessary to give a detailed description of the general characteristics of the coal mined from the

FIG 2.

Phalen seam, as they are so well known. Phalen coal is a rather friable, fat, bituminuous coal, with specific gravity of from 1.28 to 1.30. On account of its high heating value Phalen coal is in large demand for steam raising purposes, and it is a good coking coal, yielding a profitable return in bye-products when burnt in bye-product ovens.

We purpose dealing with each colliery in detail by itself, and will commence with No. 1, or as it is locally known, "Dominion."

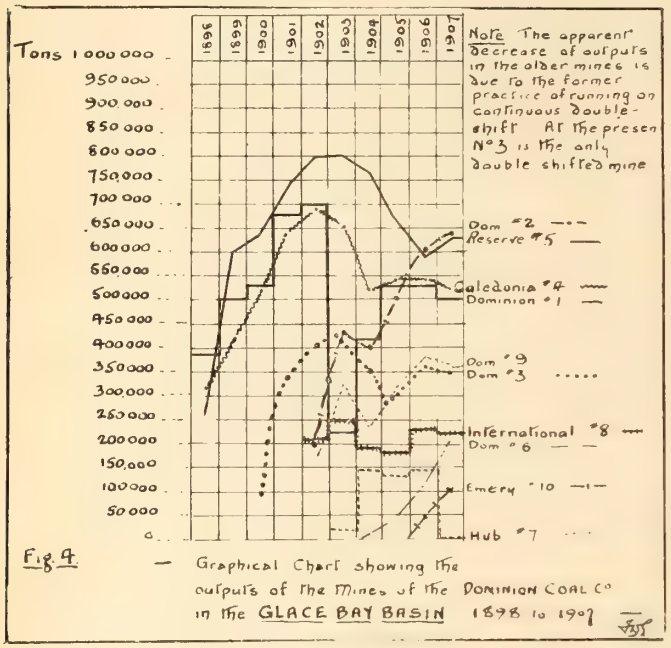

Fig 4 — Graphical Chart showing the outputs of the Mines of the DOMINION COAL Co in the GLACE BAY BASIN 1898 to 1907

Dominion No. 1 Colliery.

No. 1 colliery is the first mine that one meets in travelling over the Sydney & Louisburg Railway from Sydney to the colliery towns. It is in a district that saw the first beginnings of the Cape Breton coal trade, and is pleasantly situated overlooking Lingan Bar in the midst of a countryside that is a little more cultivated than the surrounding neighborhood. "Dominion"—not to make any invidious comparisons—has always been regarded more or less as the model colliery of the Dominion Coal Company, and its workmen, mostly life long residents of the neighborhood, are looked upon as men of light and leading, whose native conservatism is a little shocked at the crude modernity of "New Aberdeen."

The territory assigned to Dominion No. 1 was first worked at Old Bridgeport by the General Mining Association in 1830, the workings being largely confined to the crop area. The coal was shipped on the other side of Lingan Bay, being conveyed from the slopes by means of a railway that ran along the course of the Lingan sand bar. Trade proving bad the mine was abandoned by the General Mining Association in 1842, and the colliery was not operated again until 1886, when it was reopened by Mr. Henry Mitchell of Dominion, who continued to operate it under a sub-lease from the G. M. A., until his interests were absorbed by the Dominion Coal Company in 1893. The latter corporation continued mining operations at Old Bridgeport until 1898. They had erected a new bankhead at the time they took over the property, and produced from Old Bridgeport between 1893 and 1898 approximately 640,000 tons, at the end of which period they dismantled the mine.

In 1893 the Dominion Coal Company sunk the present shafts at Dominion No. 1, and equipped the colliery with modern machinery, since when Dominion has produced 5½ million tons of coal, and is at the present time hoisting between 50,000 and 52,000 tons per month on single shift.

There are three shafts, hoisting, material, and air shafts, the material shaft not being in use except for the conveyance of haulage ropes underground. The main hoisting shaft is divided into two compartments, one for hoisting coal and the other for men. It is 24 feet by 10 feet 6 inches inside the buntons, and is 158 feet deep. The cages are of the dumping type generally used by the Dominion Coal Company, running on the ordinary square wooden guides. The hoisting engine was made in Glasgow, and was installed in 1894. It is a horizontal hoist, 20 inches by 54 inches cylinders, having a drum 8 feet 9 inches in diameter with 5 feet 6 inches face. The hoisting rope is a six strand cast steel rope, 1⅜ inches in diameter, hoisting daily from 2,000 to 2,400 tons.

The man hoist was made by I. Matheson, of New Glasgow, and is a 16 inches by 32 inches horizontal engine with 6 feet drum.

The mine is ventilated through a circular air shaft 10 feet in diameter, connected with a Dixon fan of the Guibal type, 24 feet diameter with blades 6 feet 6 inches wide, 100 revolutions per minute, capacity 300,000 cubic feet per minute, at 2 WG., cased in brick and driven by a direct connected 18 inches by 28 inches "Buckeye" engine. The air shaft is used as a downcast, and the hoisting shaft as the upcast. This is the

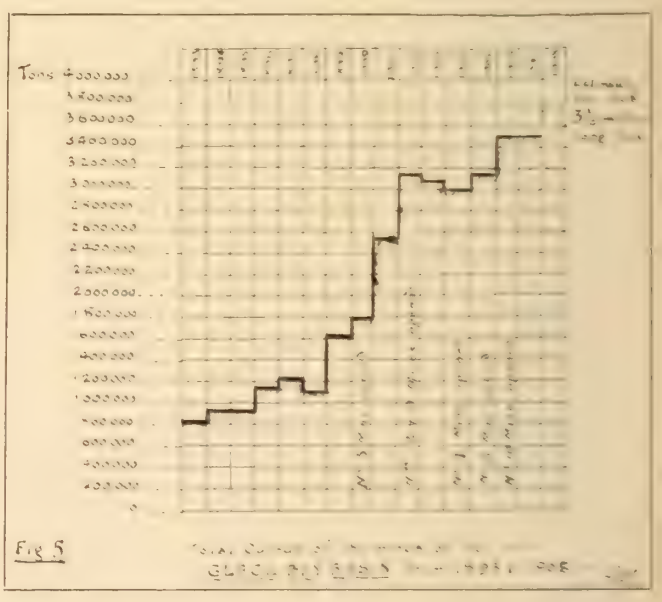

Fig 5

usual practice in Cape Breton, being so arranged in order to keep the pit mouth free from ice in the winter. The ventilation can be reversed at short notice if necessary. There are also two spare Murphy fans, 12 feet and 8 feet diameter respectively, which are not in use, but are reserved for emergencies.

The steam plant consists of seven Babcock & Wilcox boilers, having a total rated capacity of 1,696 horse power. There is one brick smoke stack 125 feet high, and one steel stack 74 feet high.

HUB MINE—No. 7 (HUB SEAM).

The haulage plant consists of two large haulage engines 28 inches by 60 inches cylinders. These engines were installed in 1901, having been formerly used on street railway traction in the City of New York. These engines operate two endless ropes, namely, the Angle Deep rope, 13,500 feet total length of 1¼ inch rope; and the South Deep rope, which is of the same diameter, and 17,500 feet in total length. The South Deep is within 1,000 feet of its full extent, and this haul will not be materially extended.

There are three Ingersoll compressors, having a capacity of 2,500 cubic feet per minute, each, two of which were installed in 1894 and one in 1900. There is also a small straight line compressor, wth a capacity of 900 feet, which was put down in 1903 at the time of the fire.

The surface and pit bottom are electrically lighted from an independent generating unit 100 kw., 250 volts.

The bankhead is a steel structure, housed with corrugated iron, and fitted with shaking screens and picking belts. It possesses no features out of the ordinary. Coal is fed directly to the boilers by two Robins belt conveyors, and there is also a small belt conveyor to the locomotive bunker pocket.

The other surface erections are those to be usually found at a colliery, and include a wash house for the men, a well equipped and new lamp cabin, and a fireman's hall, containing hose and reels, fire fighting appliances, and a parlor for the use of the colliery fire brigade in their moments of diversion. Chemical extinguishers of the "Fire King" pattern are distributed around the colliery, both above and below ground, and the fireman's hall will shortly be fitted with several Draeger apparatus, which will be kept in readiness for immediate use by the colliery rescue corps. The general fire fighting organization of the Dominion Coal Company will be dealt with fully in a separate notice.

Underground the mine is divided into two main districts, known as the South Deep and the Angle Deep. The South Deep district will work up to the barrier of No. 2 colliery, and the Angle Deep has a large submarine territory, the exact definition of which will depend upon the position of the Bridgeport Anticline, and the amount of dislocation attendant on this fold in the strata, which is as yet largely a matter of conjecture. At present the face of the Angle Deep leading place is advanced about 3,000 feet under the sea from the shore line, and about 800 tons per day of submarine coal is being mined.

DOMINION No. 2.

DOMINION No. 2.

The ventilating current is divided into two main splits at the bottom of the downcast air shaft and is sub-divided again on the south side of the mine. The Angle Deep is ventilated by a single split.

The pumping plant of the mine is as follows: One 20 inches by 8 inches by 24 inches Northey steam pump, one compound Northey pump, 12 inches and 24 inches by 8 inches and 24 inches. One six stage McDougall turbine pump, operated by power from the Central Power Station at No. 2 colliery. The steam for the Northeys is taken from the International boilers through a borehole into the Phalen seam. The three pumps discharge into a common borehole, which empties itself into the Harbour seam above, and is conveyed by means of the International water level to the shore. There is also a large Cameron pump that discharges into the sea through the opening that was made into No. 1 workings from the shore at the time of the fire. There is another large Northey pump on the surface for fire protection purposes and several other pumps for the colliery water supply.

The average force employed at the colliery is round 700 men. The horses number about seventy. The underground equipment consists of about 400 mine cars, 45 compressed air percussive pick mining machines, and about 22 "Little Hardy" shearing machines. The mine is fully equipped with Ackroyd & Best electrically lighted safety lamps, with magnetic locks. The underground workings are equipped with sufficient relighters, which are kept under individual and careful supervision.

An examination of the chart of outputs of individual mines, Fig. 4, will show a drop in the output of No. 1 in the years 1903 and 1904. This was caused by a fire, which broke out in the workings on the 19th of March, 1903, and getting beyond control, necessitated the flooding of the mine in order to extinguish the fire. The mine was unwatered on the 13th of June, 1904, but it was not until the middle of 1905 that the output regained its normal tonnage. A full description of the fighting of this fire, and the flooding and pumping operations that followed, will be found in a paper contributed to the Canadian Society of Civil Engineers by the late Shirley Davidson and Norman MacKenzie, the present superintendent of No. 2 district.

The next number of this series will deal with No. 5 Colliery (Reserve), No. 3 Colliery, and No. 4 (Caledonia).

(To be continued.)

RESERVE MINE No. 5, PHALEN: No. 10, EMERY SHAFT

THE SUMMER EXCURSION.

At our request, Mr. H. Mortimer-Lamb, secretary of the Canadian Mining Institute, has outlined the programme of this summer's trip.

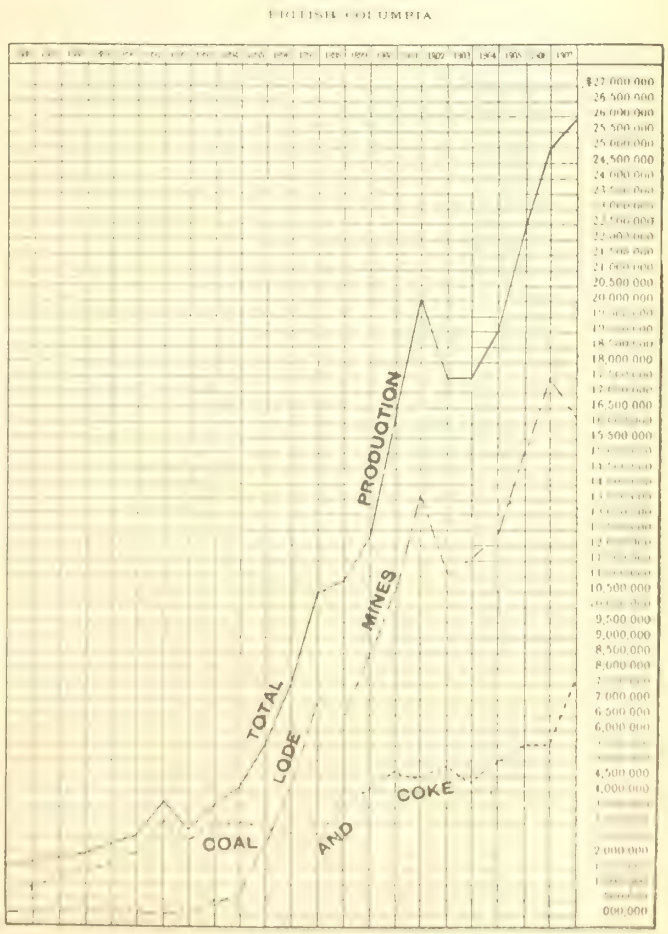
"The excursion will start from the city of Quebec either very early on the morning of August 24th (probably shortly after midnight), or early on the morning of the following day, in order that the party may have an opportunity of viewing the scenery along the Bay of Chaleur, which will thus be passed in daytime. Two whole days will be spent in Sydney visiting the steel works and collieries in the vicinity; and one day at Stellarton. Possibly the party may visit Halifax; but all the arrangements in connection with the Nova Scotia visit will be made and carried out by the Mining Society of Nova Scotia, who have kindly offered to consider the Institute and the European representatives as its guests during our stay in that province. It is designed that we shall reach Sherbrooke on Monday morning, August 31st, and leave immediately by the Quebec Central for Thetford and Black Lake, where a day will be spent visiting the asbestos mines. Leaving Sherbrooke early in the morning of Tuesday, September 1st, we arrive in Montreal at noon and spend a day and a half in the city, leaving for Toronto at 10. p.m., on September 2nd. On September 3rd, an ex-

cursion will be made to Niagara Falls, while on the 4th, the party will have an opportunity of visiting the Toronto Exhibition and will be entertained at luncheon by the directors. Leaving Toronto that night, we proceed, via North Bay, to Cobalt and will spend a day there, leaving in the afternoon of September 6th for Copper Cliff, and spending the evening of that day in Sudbury. It is then proposed to have the cars taken, during the night, to Moose Mountain, where the morning of September 8th will be spent. We then go on to Winnipeg, arriving at night on the 10th, and leaving the following morning at noon. At Medicine Hat, a special train will be chartered to take the party as far as Lethbridge, and on the 13th we visit Frank and Blairmore; on the 14th, Fernie; on the morning of the 15th, the St. Eugene at Moyie, arriving at Rossland that same night. A day will be spent at Rossland, and on the 17th, a visit will be paid to the Trail smelter en route to Nelson. Friday, September 18th, will be devoted to visiting Bonnington Falls, and to points of interest in the vicinity of Nelson. Two days will then be spent in the Boundary district, whence the party will journey direct to Victoria, where two days will be spent, leaving on the evening of the 25th of September. After spending a few hours in Vancouver, we are due at Banff on the evening of Sunday, September 27th. At Banff, the party will possibly be entertained at luncheon or dinner by the Government of Alberta. On the return journey, it may be possible to arrange for a visit to the Atikokan iron mine and furnace. The programme, as at present arranged, contemplates the arrival of the party at Montreal on October 2nd.

"The above in brief covers the arrangements as so far made, but details, of course, have yet to be worked out. Upwards of ninety provisional acceptances have been received from members of the several British societies to whom invitations were issued; while in addition, several members of these societies residing in the United States, have also signified their intention of participating. It is scarcely likely, however, that all will come, but definite assurances are expected not later than July 1st. It depends on the number of persons taking part whether, or not, we shall be able to charter a special train for the whole trip, but meanwhile, the railway companies have offered a special rate of half fare. Great interest is being manifested in the excursion to Great Britain, and it may be noticed that at the recent annual dinner of the Institution of Mining and Metallurgy special reference was made to it in a speech by Earl Crewe."

Annual Report of the Provincial Mineralogist Upon the Mining Industries of British Columbia for the Year 1907.

The year 1907 saw the greatest total production on record from the mines of British Columbia. Early in 1908, the "Canadian Mining Journal" gave an abstract of the mineral output The report before us, however, contains a great deal of material that demands attention.



By the established custom of the Provincial Bureau of Mines in estimating the output of the lode mines, the output of a mine for a year is considered as that amount of ore for which smelter or mill returns have been received. This, obviously, does not include all of the ore mined. December ore shipments to the smelter are usually carried over to the new year. This gives rise to but a small error, as where necessary, it is uniformly carried over from year to year.

In calculating the values of the products, the average price for the year in New York has been used as a basis. For silver 95 per cent., and for lead 90 per cent., of such market price has been taken. Treatment and other charges have not been deducted.

The increase in value of mineral production of 3.6 per cent. over 1906 is due to the greater tonnage of of low grade ore mined in the Boundary district and to increased tonnage from the collieries. The total for 1907 is $25,882,560 The high market price of metals in the former half of the year was offset by low prices in the latter half.

The tonnage of ore mined during 1907 was 1,804,114 tons, of which the Boundary district produced 65.1 per cent.; Rossland, 15.8; Coast, 4.7; Fort Steele, 8.6; and all other districts 5.8.

Of 147 shipping mines, only 72 shipped more than 100 tons each.

Two thousand, five hundred and eighty-five men were employed underground and 1,112, overground in these mines.

Sixty-one non-shipping mines employed 119 men underground and 127 overground.

Up to the end of 1907, British Columbia has produced coal to the value of $86,972,511, placer gold to the value of $69,549,103 and lode gold to the value of $45,070,717.

The total mineral production for 1907 was more than double that of 1899. The value of the total products of the mines of the province up to the end of 1907 is $299,526,282.

For twenty years coal mining has been a constantly increasing industry. Lode mining, beginning in 1894, has now risen to the $17,000,000 mark, but has been subject to many fluctuations.

Coal.

The fall in silver and lead production, in fact in both branches of gold production and copper also, was more than compensated for by the increased quantity of coal mined. One million, eight-hundred thousand and sixty-seven long tons of coal valued at $6,300,235; and 222,913 long tons of coke valued at $1,337,478 were the figures for the year. The gross output, however, was higher than this, being 2,219,608 long tons of coal. Of this quantity, 44,760 tons were added to stock; 916,262 tons were sold for consumption in Canada; 673,114 tons were exported. Thus the total coal sales for the year were 1,589,376 tons. Of the balance, 419,541 tons were used in making coke and 165,931 tons under colliery boilers.

The Coast collieries mined in 1907 some 1,342,877 tons of coal. Of this, 44,760 tons were added to stock, bringing the coal distributed down to 1,298,117 tons, thus:

	Tons.
Sold as coal in Canada	698,041
Sold as coal in the United States	359,666
Sold as coal in other countries	22,038
Total used as coal	1,079,745
Used under companies' boilers, etc.	121,701
Used in making coke	96,671
	1,298,117

The home market showed an increase of 31.4 per cent. over last year; the United States market a decrease of about 17 per cent.

The Crow's Nest Pass Coal Company, the only operating company in the Rocky Mountain coal field, mined 876,731 long tons during 1907, of which the following distribution was made:

	Tons.
Sold as coal in Canada	218,221
Sold as coal in United States	291,410
Total sold as coal	509,631
Used by company in making coke	322,870
Used under company's boilers, etc.	44,230
	876,731

The amount of coke made from the 322,870 tons of coal used was 206,541 tons (2,240 pounds), of which 5,664 tons were carried over as stock and 200,877 tons sold, 140,987 tons for consumption in Canada, and 59,890 tons exported to the United States The oven yield of coke was 63.9 per cent.

Gold.

Placer gold production for 1907 was about $828,000, a decrease of $120,400 or 12.7 per cent., as compared with 1906. The Atlin district is the principal producer. Three -hundred and forty thousand dollars worth of gold paid royalty here during 1907. The Cariboo district produced $350,000. Dease Lake in the Stikine district, was a disappointment. The lower Fraser and the Thompson river produced practically nothing.

The value of the gold produced from lode mining in 1907 was $4,055,020, a decrease of $575,619 or about 12.5 per cent. About 95 per cent. of the gold is recovered from smelting copper-bearing ores. The only stamp mill of any importance is at Hedley, in the Osoyoos mining division, which mined and milled about 32,000 tons of ore, from which was recovered about $475,000.

Silver.

The total silver output for 1907 was 2,745,448 ounces, valued at $1,703,825, a decrease of 244,814 ounces and $193,495 in value.

About 72 per cent. of the silver produced is found associated with lead, in argentiferous galena, the remainder being found in conjunction with copper-bearing ores.

The Slocan district, including Ainsworth mining division, provided 32 per cent. of the total Provincial output, and Fort Steele mining division 30 per cent., all from argentiferous galena.

Lead.

Forty-seven million, seven hundred and thirty-eight thousand, seven hundred and three pounds of lead, valued at $2,291,458, were produced, a decrease of 4,669,514 pounds and $376,120 as compared with 1906.

	Pounds	Per cent of Total.
Fort Steele mining division	37,526,144	= 78.61
Slocan	4,305,826	= 9.00
Ainsworth	3,654,775	= 7.66
Nelson	1,582,113	= 3.32
All other districts	669,795	= 1.41
	47,738,703	100.00

Copper.

The output of copper for 1907 was 40,832,720 pounds, having a gross value of $8,166,544. As the larger coper-producing mines were only run for nine months, the output is slightly smaller than for the preceding year.

	1907 Pounds	Per cent.
Boundary district	31,521,550	= 77.2
Rossland district	5,080,275	= 12.4
Coast and Cassiar district	3,757,967	= 9.2
Yale-Kamloops district	36,120	= 0.1
Nelson district	434,222	= 1.1
Other districts	2,586	= 0.0
	40,832,720	100.0

Other Minerals

Practically no iron ore was mined, with the exception of 1,500 tons of bog iron ore mined and shipped

from Quatsino sound. The deposit was found too shallow for profitable work.

Zinc ore mining was stationary. The Lucky Jim mine in the Slocan, shipped 1,120 tons of ore mined in 1906, but no fresh mining was done. Zinc blende concentrates from Slocan district were produced but neither sold nor treated. The Legislature advanced $10,000 to aid in completing the Nelson plant of the

ROCK FORMATION—ENTRANCE IKEDA BAY, Q.C.I.

Canada Zinc Company. The power for this plant is obtained from Bonnington Falls.

The building stone and brick industries are increasing. Fire brick, fire clay, lime-silica brick, lime and cement are the bases of incidental activities.

The staff of the Bureau consists of the Provincial Mineralogist, the Provincial Assayer, a junior assistant in the Laboratory, and a clerk as temporary assistant during the publication of the Report.

The Provincial Mineralogist visited Ashcroft, Highland Valley, Nicola Valley, Quatsino Sound, Queen Charlotte Islands, Atlin and other districts during the summer.

In May and in December the examinations for assayers were held.

Assay Office.—During 1907 assays are quantitative determinations to the number of 905 were made. Total cash receipts were $1,057. A large number of free qualitative determinations were performed. Only 4 candidates for asayers' certificates wrote on the examinations. Three were successful.

The "Coal Mines Regulation Act" provides that all the officers of a coal mining company having any direct charge of work underground, shall hold Government Certificates of Competency, obtainable only after passing an examination before the Managers' Board. These certificates are First, Second and Third, respectively Manager's, Overman's, and shiftboss, fireboss, or shotlighter's certificate. From three to five years' practical experience is called for before candidates are eligible for examination. Fifty-two out of 56 candidates were successful.

Cariboo District.

A slight increase in the hydraulic gold output was recorded for this district. Coal was discovered in Bear River, about 15 miles from the Fraser. In Quesnel mining division of this district the Consolidated Cariboo Hydraulic Mining Company's property at Bullim, taken over by the Guggenheims in 1906, was abandoned by them.

Cassiar District.

Atlin mining division had a good year. Although 100 fewer men were employed the gold output was not materially reduced. Scarcity of water and labor interfered with what should otherwise have been an unusually good season.

The Stikine and Liard mining divisions had an exceptionally light year.

In Skeena mining division are the Queen Charlotte Islands. The mining activities on Moresby Island have been described in the "Canadian Mining Journal" of recent date.

The other mining districts to the south are reported upon and their year's progress recorded. We need not go over these. They have had regular attention in our columns.

Accidents.

In the metalliferous mines of British Columbia there were 94 accidents in 1907. Out of this total 20 were fatal, 20 serious, and 54 slight. Of the fatal accidents, four were attributed to drilling into old holes containing powder. One serious and one slight accident are also set down to the same cause. The source of the largest number of underground accidents (most of which were slight) was falling rock in stopes, levels, etc. For each 100,000 tons of ore mined there was a total of 5.22 accidents (1.11 fatal, 1.11 serious, and 3.00

NO. 2 TUNNEL, LILY GROUP, IKEDA BAY, MORESBY ISLAND.

slight). For each 1,000 men employed there were 25.4 accidents (5.4 fatal, 5.4 serious, and 14.6 slight).

Looking up the corresponding tables for 1906 we find that there were in that year fewer accidents, only 60 altogether. For each 100,000 tons mined in 1906, only 3.06 accidents occurred, of which only 0.86 was fatal. For each 1,000 men employed there were 15.38 accidents of all classes, 4.61 of which were fatal.

The collieries of the province recorded 154 accidents for the year—31 fatal, 61 serious, 62 slight—a greater number than has occurred since 1902.

Falls of coal were responsible for 8 fatal accidents. Mine car fatal accidents reached the same number and both serious and slight accidents due to this cause, exceeded those from all other individual causes. Explosions of gas caused but one death. There were 6,059 persons employed and 2,219,608 tons of coal produced.

ORES AND ROCKS OF THE COBALT REGION.

By R. E. Hore.

The exploration of the larger areas of silver and Cobalt bearing rocks has disclosed new types of deposits, and has afforded additional information regarding the origin of the deposits and of the rocks containing them. It is the purpose of this article to give some results of study in field and laboratory.

In Coleman township interpretation is difficult on account of the variety of formations—Lower Huronian sediments, Keewatin volcanics, and Post-Middle-Huronian Diabase—in which the silver-cobalt deposits occur. In other parts of the area a less promiscuous distribution of the ore has been found.

The deposits in Casey Township are in Lower Huronian, a few hundred feet from diabase. Those of Pense and Ingram townships are confined to diabase, as are also those in the Elk Lake and Anvil Lakes districts of the Montreal River Mining Division, and the deposits of Portage Bay and Anima Nipissing. Lately discovered deposits south of Lorrain township are said to be in rocks of Keewatin age.

The Diabase.—The intimate connection of the ore deposits with this rock becomes more and more apparent as prospecting advances. For some time it has been the "nishishin sini" of the prospectors. It occurs for the most part in large sills of a few hundred feet in thickness. In the Temagami Reserve the writer has examined a large number of diabase hills which stand from one to two hundred feet above the surrounding country. In several instances the contact with greywacke slate was found, and in all cases it is near the base of the hills. Since the texture of the diabase at the summits is generally quite coarse, it is probable that the original thickness was at least double the height of the present hills.

For the most part the sills are dark grey in color and holocrystalline, the chief minerals being plagioclase feldspars labradorite in many cases) and monoclinic pyroxene. Quartz and ilmenite are frequently present. Near the edge of the sheet it is very fine grained and ophitic texture is more pronounced; but the grain becomes quite noticeable a few feet from the contact. In more coarsely grained portions, often pink in color, quartz is more abundant and generally is found in micrographic intergrowth with feldspars. In petrographical character and in its relation to the Huronian sediments, the diabase is remarkably similar to those of Lake Superior which are regarded as Keweenawan,[1] being the plutonic contemporaries of the copper bearing lavas, or as post-Keweenawan in age.[2]

Veins in the Diabase.—Veins in these sills are not common, and quartz veins are more abundant than calcite. In Coleman township the rich veins have little gangue mineral, in some cases native silver occurring simply in thin sheets along the joint planes; but what little gangue there is is calcite. In other areas some of the quartz veins are cobaltiferous; but the valuable deposits as a general rule have calcite gangue. Argentiferous galena occurs in some of the quartz veins west of Wakmika Lage, along with pyrite and chalcopyrite and a later filling of pale pink calcite. In the Elk Lake district barite veins are said to be argentiferous. All the veins are vertical or nearly so, and probably represent fillings in tensional joints due to cooling and contraction of the igneous sheet.

Intrusives in the Diabase.—There occur in the sills small dikes, some more basic, others more acid than the main mass. In Coleman township there are fine grained dark colored dikes of olivine diabase, while near Temagami there are narrow dikes of diabase porphyry.

More frequent, and of greater economic interest are the light colored aplites. The width of most of these is to be measured in inches, while in length, they are but a few hundred feet. They are frequently mineralized, pyrite, chalcopyrite and galena being present in many, while silver and cobalt minerals have been found in them in the Elk Lake area. They are composed largely of quartz, orthoclase and acid plagioclases; but the proportions vary considerably in the same dike. There is considerable chlorite in darker colored portions, and calcite fills interstices between the other minerals. Small crystals of titanite and apatite are inconspicuous but characteristic constituents.

Disseminated Ore in the Diabase.—In the diabase which extends westward from Anima-Nipissing to Lady Evelyn Lake there are numerous showings of cobalt minerals, both in calcite veins and as disseminated crystals in the rock. There is generally little or no surface indication of the presense of the latter; but on fresh fractures traces of cobalt bloom are found. One deposit, west of Diabase Lake, is associated with an aplite vein. The vein contains some pyrite, but little smaltite. Parallel to the vein for a few feet from its walls the diabase contains disseminated crystals of smaltite, which are more concentrated near joint planes. The chief primary constituent of the ore-bearing rock is feldspar. The smaltite crystals are embedded in calcite and chlorite, and are accompanied by small crystals of titanite.

Another cobaltiferous specimen from this region shows some kernels of augite still undecomposed, and a remarkably high percentage of ilmenite.

Origin of Disseminated Ore.—To the naked eye the detection of smaltite in the diabase suggests the possibility of its being an original constituent. The altered character of the ore-bearing portions and the association with aplite, suggest that the ore had its origin in the gases or hot solutions which accompanied these late secretions of the cooled differentiated magma.

Microscopic examination shows that the smaltite is embedded in secondary minerals and seldom in the undecomposed feldspar. In the latter case high magnification shows numerous small cracks in the feldspar. Some of these are filled with calcite and apparently have acted as channels to introduce the smaltite, so that the latter is secondary.

The absence of augite and the presence of chlorite, which is probably the result of decomposition of the former, suggests that the augite is cobaltiferous; but a specimen of the rock showing augite cores was found to contain no trace of cobalt.

Lower Huronian.—These rocks, like the slate-conglomerate of the original Huronian area north of Lake Huron, represent the result of disintegration and de-

composition of Laurentian and Keewatin. Quartz and great degree of chemical decomposition. Quartz and feldspars are the chief constituents, while chlorite and micas are more abundant in dark colored types. Calcite is seldom found except in the vicinity of veins and apparently did not play an important part in cementing the sand grains.

It has been stated[3] that these rocks are the debris of Keewatin rocks and so play a similar role in formation of the ore deposits, especially in supplying the calcite gangue. The rocks are indeed of such a character that they represent more nearly than do some sediments the composition of the rocks from which they were derived. The very process of their formation, however, would remove some of the more soluble constituents in solution, thus making a deposit relatively inactive, since of more stable and less soluble constituents. Perhaps a more important cause of difference is that the acid igneous rocks of the Laurentian must have contributed largely to the Huronian sediments. It follows, therefore, that if, in virtue of their mineralogical composition, the Keewatin volcanics play an important role in the ore deposition, the Huronian sediments play the same role in but a minor way, if at all.

It is sometimes stated[4] that there is reason for believing that much of the Huronian rocks is of volcanic origin, and represents consolidated ash. If this were true there would be doubtless present many constituents that are unstable in the zone of weathering. Permeating waters would cause many chemical changes, and resulting solutions would be important factors in ore deposition. The rock specimens examined, however, do not show fragments of glass nor minerals characteristic of volcanic tuffs, and there is no conclusive evidence of igneous material introduced contemporaneously with the Lower Huronian sediments.

There is evidence[5] that some of these sediments are glacial deposits. Such material represents very closely the composition of the original rocks. The chief difference between these deposits and the Keewatin rocks would be in their disintegration (and consequently greater ease of decomposition) and admixture with debris of the Laurentian. The examination of a large number of unconformities shows that the basal conglomerate and the underlying surface are by no means similar to that of glacial deposits, while the regular gradation from feldspathic quartzite to the upper conglomerate beds is also not easily explained by that hypothesis. On the other hand, the boulders of the upper conglomerate may be the erratic deposits of drifting ice. It seems likely that glacial debris, if present at all, forms but a small proportion of the sediments.

These rocks then, although not extreme types of weathering, are composed largely of minerals that are stable in the zone of weathering and are far less active than the Keewatin volcanics in ore deposition.

Keewatin.—In Coleman Township this formation is chiefly represented by dark colored, fine grained, basic volcanic rocks. In Harris and in Tudhope there are outcrops of the same nature. Sedimentary types, as well as igneous, are represented at Larder Lake by the auriferous carbonates and at Temagami by carbonates and iron-bearing cherts. The writer has not yet seen cobalt deposits in diabase or carbonates where these are closely associated. This suggests that the volcanic rocks supplied elements other than the carbonate gangue.

The numerous rich veins in Keewatin at Cobalt are not far distant[6] from the diabase sill, while in some cases a vein traverses both formations. The veins in Huronian are in no case more than a few hundred feet from Keewatin. On the other hand numerous areas of greywacke in contact with diabase where there are no Keewatin exposures have always proved barren, even though the diabase is known to be cobaltiferous, as at Lake Wendigo. The same is true of the feldspathic quartzites of Anvil Lake and James Township. The conclusion is that the Keewatin volcanics are an important factor in the ore deposition.

Conclusion.—The ores originate in the diabase. While it has been shown[7] that silver is deposited later than cobalt minerals, the occurrence in aplite indicates that there was no great time interval. Keewatin volcanics assist in the ore deposition, while the Lower Huronian sediments are relatively inactive. The part played by the Lower Huronian is primarily that of a recipient for the ores, and, by virtue of their regular vertical jointing, they carry more valuable deposits than do the irregularly fissured Keewatin rocks.

Prospecting should be fruitful in areas which show Keewatin volcanics in association with the Diabase sills, and especially so where Lower Huronian sediments are also present. There is little doubt that there are many such occurences between Lake Temiskaming and Lake Huron.

THE CHAMBERS-FERLAND MINING COMPANY'S PROPERTY.

A long protracted dispute as to the ownership of the Chambers-Ferland property was settled last year. The title was secured to the present owners; but the government imposed a royalty of 25 per cent. on the future output of the mine. Last summer a certain amount of surface prospecting was performed. Otherwise, beyond two shafts now being sunk, there is no development work done.

The organization of the Chambers-Ferland Company and the announcement that shares are soon to be placed upon the market, have created much interest. Following hard upon the heels of the La Rose flotation, Chambers-Ferland will undoubtedly receive much attention.

Because of this, the "Canadian Mining Journal" has got together all available information and, is presenting it to its readers, with the object of giving them as impartial an account of the property as it is possible to obtain.

The holdings of the company comprise 124 acres practically surrounding La Rose. As will be seen by the cut accompanying this article, the property is bounded on the south and east by La Rose extension, on the southeast and north by the O'Brien and La Rose, on the west and south by the Right of Way, Nipissing and O'Brien mines.

Although, as remarked before, very little work has been done on the Chambers-Ferland, yet, because of its position, definite results have been obtained from the little done.

For instance, the main vein of La Rose has been traced across the Right of Way over onto this property. An extension of the O'Brien main vein has been cut and a seventy-foot shaft has developed a fair body of ore. Besides these veins there have been at least nine other so-called veins cut, some displaying high-grade ore and some otherwise.

The preponderating number of veins found in the Huronian throughout the district has led to the conclusion that properties lying in this geological horizon are more valuable than others not so situated. With the exception of a few acres all of the holdings of the Chamber-Ferland lie in Huronian. Hence prospecting will be conducted with a strong expectation of good results.

Mining should be reasonably cheap as eight or nine veins, grouped on either side of one shaft will be worked together. Not all of these veins are payable, neither is there good ground for the statement that ore shoots on contiguous properties are continuous for over 1,000 feet. As a matter of fact, there is no evidence that would lead one to postulate ore shoots of more than a few hundred feet. However, such ore shoots are found to recur in close succession. This fact, applied to Chambers-Ferland will modify any speculative estimates to ore reserves. Positive reserves, of course, there are none. But the developments in La Rose, O'Brien and Nipissing lend a value to Ferland-Chambers possibilities. Although "ore in sight" is a phrase applicable only to bodies developed on three sides, yet the next best thing is ore from veins traversing a property from developed neighboring mines. In other words, high probabilities have a commercial significance only second to established fact.

We have seen no estimates touching the probable cost of mining the cost and visible supply of timber, the cost of the necessary machinery, and buildings. These and many more such facts should be included in the report and given to the public.

Several Cobalt mining engineers when asked for an opinion regarding Chambers-Ferland, spoke very highly as to its possibilities. This is well. An opportunity is now before the promoters of the flotation to set a standard for clean and business-like methods. If advertisements are necessary, let them be couched in decently moderate language. Also let them, in every respect, conform to the requirements of the Companies' Act. Moreover, reports of progress, expenditure, and income should be made public at regular intervals.

The capital of the new company is $2,500,000, in shares of the par value of $1 each. Three hundred thousand dollars is to be reserved as treasury stock. The officers and directors are: President, W. C. Chambers; vice-president, Harper Armstrong; secretary-treasurer, Alex. Fasken; directors, W. B. Russell, Arthur Ferland, George H. Sedgwick and Archibald T. Struthers.

THE OCCURRENCES OF TUNGSTEN ORES IN CANADA.

By T. L. Walker, University of Toronto.

(Ottawa Meeting of the Canadian Mining Institute, March, 1908.)

In 1904 the Geological Survey of Canada issued a bulletin on the occurrence of molybdenum and tungsten[1] in Canada. At that time the known occurrences were the following: Inverness and Queens Counties, N. S., Beauce County, P. Q., and a reported occurrence of wolframite in a boulder on Chief's Island, Lake Coutchiching, Ontario. More recently[2] Mr. R. A. A. Johnston, curator of the Geological Survey's museum, has recognized scheelite in the heavy sands from gold washings in the Yukon, while wolframite, scheelite and hubernite have been found in the tin deposit near New Ross, Lunenburg County, N. S.

Occurrences Already Recorded.

Slocan district.—In the reports of the Minister of Mines for British Columbia several localities have been indicated. The report for 1903[3] mentions the discovery of masses of scheelite occurring in vein quartz in the form of lenses at the Meteor mine in the Slocan district. The lenses vary in length from one to three feet, a total of 500 pounds being saved after the identification of the mineral.

In the subsequent reports of the Minister of Mines no reference is made to the production of scheelite in this district. The occurrence of scheelite or of other tungsten minerals in silver lead veins is unusual.

Cariboo district.—In 1904 an important discovery of scheelite was made on Hardscrabble Creek in the Cariboo district. Mr. Akin first discovered this mineral in the black sands obtained in gold washing and later succeeded in locating the scheelite in place. He describes the geological occurrence as follows:[4]

"This consists of highly altered country rock, the scheelite being scattered through it in small patches, but it is in the quartz stringers that most of the mineral is found. Some of these, varying from one inch to four inches wide, contain about one-third scheelite, with a little galena, and products of decomposition of iron pyrites. This zone appears to be from 12 to 20 feet wide, as determined by work done up to July, 1904, and gives every promise of turning out a valuable deposit."

After experimenting on the concentration of the scheelite by washing, a quantity was sent to Chicago to be tested and as a result of these tests was stated to be worth $460 per ton at the prices then current.

Promising as this report seemed it does not appear from the later reports of the Minister of Mines to have been followed by active development.

Occurrences Not Previously Reported.

Wolframite—Sheep Creek, B. C.—In the vicinity of Salmo in British Columbia some of the gold quartz veins carry considerable proportions of wolframite, specimens of which were collected recently by the writer from mines on Sheep Creek. The wolframite on ex-

amination in the laboratory was found to have a specific gravity of 7.137. With it are associated ferruginous quartz and wherever the mineral has been exposed to secondary action, yellow more or less powdery tungstite occurs. On chemical examination the following result was obtained:

WO_3	74.90
FeO	17.75
MnO	2.75
CaO	1.52
MgO	2.66
SiO_2	1.02
Total	100.60

So far as I am aware no economic use has been made of this material. I had not an opportunity of examining the mode of occurrence personally, the material being given me as coming for the Kootenay Belle mine, though its nature and value appear to have been unknown at the time.

Tungsten and scheelite.—Sheep Creek.—The writer has elsewhere[4] described in detail the occurrence of masses of hydrated oxide of tungsten in the gold quartz veins of the Kootenay Belle mine. The tungstite appears in more or less reniform concretionary masses in the vein associated with wolframite and scheelite, from which it was derived by alteration. In the tungstite specks of native gold may be observed. It was as gold ore that this auriferous tungstite along with the accompanying gold quartz was shipped. I have reason to believe that in the subsequent treatment the tungsten values were not recovered even when they were very much more valuable than the gold contents.

From an analysis of the tungstite-wolframite-scheelite ore in the laboratory the following results were obtained:

	Per Cent.
WO_3	86.20
FeO	1.20
CaO	.54
Fe_2O_3	4.14
Water	7.72
Total	99.81

The tungstite is golden yellow in color and very heavy—pure tungstite 5.517 and of some of the ore specimens nearly as heavy.

St. Mary's River, B. C.—Recently Mr. E. Walter Widdowson, assayer of Nelson, B. C., showed me a very fine specimen of crystallised wolframite from the St. Mary's river north of Cranbrook. I do not know anything of the quantity of this mineral available and am unable to say whether it be an economic deposit or not.

Scheelite from Victoria Mines, Sudbury District, Ontario.—At the Victoria mines of the Mond Nickel Company in 1904 Mr. T. M. Paris, assayer for the company, presented to me a few small fragments which he had determined as scheelite. I do not know anything as to the mode of occurrence, but so far as I know this is the only place in the Sudbury dictrict where tungsten mineral has ben found. The general studies of the genesis of the Sudbury ore deposits lead us to anticipate the occurrence of such minerals as scheelite.

The mineral is quite white and of very vitreous lustre; specific gravity 6.167. On the fragments in my possession no crystal surfaces are visible, but from the continuous cleavage surfaces it is probable that they are crystal fragments.

A chemical analysis showed that the mineral is exceedingly pure.

	Per Cent.
WO_3	79.36
CaO	19.96
Total	99.32

Conclusion.—The ever increasing importance of tungsten in the industries calls for an examination of these various Canadian occurrences with a view to determining their possible economic value. Within the past year the government of the United States has appointed an officer to examine and report on such occurrences within their borders. In Canada we know of tungsten minerals only as specimens and curiosities and as those engaged in developing properties do not know these minerals or their value, such an appointment might be beneficial in many ways.

A NEW IRON ORE FIELD IN BRITISH COLUMBIA.

By John E. Hardman, S.B. Ma.E., Montreal, Que.

Ottawa Meeting Canadian Mining Institute, March, 1908.

The discovery of large deposits of iron ore near the shore of the Bay of Chaleur, in the province of New Brunswick, in formations belonging to the Pre-Cambrian, or Cambro-Silurian, period comes as a surprise both to geologists and mining men, who hitherto may have regarded New Brunswick as containing less profitable mineral wealth than any of the other provinces. When to this statement is added the further one that, the present facts indicate the probability that this district contains as large, or larger, deposits of merchantable iron ore as have hitherto been found in the Dominion, there will be no excuse needed for presenting to the notice of this Institute a preliminary, and somewhat fragmentary, account of the field.

No geological reconnaissance of this portion of New Brunswick has been made (so far as the publications of the Survey show) since the seasons of 1879 and 1880, when Dr. R. W. Ells examined the district as well as could then be done by canoe traverse of the principal streams which flow into the Bay of Chaleur. The county of Gloucester was then, and in parts is to-day, a wilderness which is traversed in the winter only by

trappers and lumbermen, and in the summer time by sportsmen, for the river and its tributary streams have long been choice ground for salmon and trout fishing.

The district under consideration lies approximately along the meridian of 65 degrees 50 feet West Longitude, and the parallel of 47 degrees 25 feet North Latitude, and is near the southern boundary of the county of Glouchester. The limits of the field have as yet been by no means defined or determined, but may be taken, according to present knowledge, as having an extreme length of some 20 miles north and south, with a width of not less than 5 miles. This extreme length takes in the field on the "Mill Stream" (so called) lying some 8 to 9 miles northwest of the town of Bathurst, as well as the portion, which is hereafter described more fully, on the northern bank of the Nipisiguit river. The larger section has an area of approximately 30 square miles. There is a linear gap of about 16 miles between the Nipisiguit area and the small area on the Mill Stream.

The rocks in which these deposits of iron ore are found are all metamorphosed or crystalline. They have been mapped as Pre-Cambrian,and belong, probably, to one of the Huronian members.

In a general way they consist of micacaeous and chlorite schists and slates with some quartzites. They are infrequently cut by small veinlets of quartz, and are also infrequently penetrated by dikes of jasper.

The surface rock about the outcrops is a mica schist, but the immediate hanging wall of the deposit is igneous, being a gabbrodiorite; the underlying rock or foot wall is a completely altered rock showing,under the microscope, only chlorite and muscovite, and its origin is uncertain, but is suggests (as is shown in the hanging) that it comes from a true volcanic.

The foot wall rock is filled with cubic crystals, both large and small, of pyrite on the edge near the body of iron ore, but its lower portion is more free from this metallic sulphide. The structural and stratigraphical relations remain to be worked out.

The designation of the ore found in this field is best given by the words "Magnetic-hematite." It has, as a rule, the characteristic cherry red streak and dark grey color of hematite, but in spots and in the vicinity of jasper intrusions is altered to a black ore which is magnetite. As a rule the ore is attracted by the magnet, a frequent characteristic of many grey specular ores. The magnetism, however, does not permeate all portions of the ore body, but is most frequently noted in the vicinity of the small intrusive veinlets of quartz and jasper which here and there penetrate the ore mass; in such places the ore has been convertd into a strict magnetite which gives the characteristic black streak, but remote from such intrusions the red streak of hematite is everywhere noted.

At the northern edge of this field (on the Ellis property) the only ore seen is a grey specular, which has not been exploited, but which appears to be more steeply inclined and to have a width of not over 5 or 6 feet.

The shore of the Bay of Chaleur contains a narrow strip of rocks belonging to the lower and middle Carboniferous, which is followed to the south by red and purple shales and sandstones which represent, probably, the Mill Stone Grit, as they are followed by, and include some of, the typical coarse grey sandstones of the Grit. This Carboniferous system extends along the eastern bank of the Nipisiguit river for 13 or 14 miles, but the western bank shows only the old granites and gneisses of Laurentian Age for the same distance. The inclination of the Carboniferous is very slight, the average running from 3 to 4 degrees from the horizontal. Above, or to the south of, the Laurentian and lying directly upon the granite are reddish and grey schists and slates, shading into blue or black slates which, in places, are highly disturbed and occasionally cut by quartz veins which render the schists more quartzose and less feldspathic. Frequently the black slates are ferruginous with pyrites, and in places the silicification has formed hard green quartzites whose color is doubtless due to a mixture of chlorite.

It is in this series of altered schists and slates that the iron beds occur. Twenty-eight years ago these schists and slates were provisionally regarded as "Cambro-Silurian" or portions of them as "Pre-Cambrian." Although unaltered eruptives were not noticed in the field the microscopic examination of the hanging and foot wall country indicate their presence in the vicinity.

Geological exploration of the region is exceedingly difficult owing to the dense growth of timber which covers it, and to the frequent patches of thick moss which cover the rock exposures. Undoubtedly a field party will be put into this new district during the coming summer in an endeavor to more clearly define the probable limits of the field, and to make a correct section, if possible, of the rock series in which the ore occurs.

Geography and topography.—The property lies about 21 miles from the town of Bathurst in a southwesterly direction, and on the north bank of the Nipisiguit river. The country rises quite rapidly in this distance, so that the elevation of the beds is about 450 to 500 feet above the sea level. Going southwest the country rises steadily until the hills of this section are reached, which vary in height from 800 to 1,500 feet above the sea level. The general character of the country is hilly and broken, with stretches of level lands along the main river. The general direction of the slight elevations which give a rolling character to the country is northwest and southeast, and across these ridges, with a general strike of nort northeast, run the bands of the formation which carry the iron ore, and which in consequence are sometimes exposed along the crests of the ridges.

Discovery.—The first discovery of ore in this field dates back to the year 1902, when Mr. William Hussey, of Bathurst, in attending some traps which had been set on Austen Brook (a tributary of the Nipisiguit River) hurt his foot upon a rock beneath the snow which turned out to be a piece of float ore from the crest of the hill nearby. The heavy character of this small boulder puzzled Mr. Hussey, who knocked off a piece and took it home with him, where it was shown to one or two people, and, by the kindness of Mr. T. M. Burns, was taken to Fredericton for examination by a Provincial Government official there, who at once pronounced it to be iron ore of a fairly good quality.

The previous history of iron ore deposits in New Brunswick had not been such as to make their mining particularly attractive as a venture, and it is not therefore surprising to find that little interest was shown in the matter. I am informed that a representative of the Dominion Iron and Steel Corporation visited the locality a few years ago, but saw only the scattered and comparatively small outcrops in the area which is now designated as "No. II." I am also informed that this

gentleman entertained a favorable opinion from the small surface exposures he was then able to see. But, in the winter of 1905, when in the same locality, Mr. Hussey remembered his previous mishap and and made a short but more thorough examination of the region, with the result that he found other outcrops and an abundance of fragments or boulders of ore on the southern bank of Austen Brook. This convinced Mr. Hussey and Mr. Burns that the ore was distributed over a quite extensive area, and these gentlemen secured rights to search upon several five-mile locations in this district.

Through the assistance of friends, advice was received from Dr. Eugene Haanel, the Dominion Superintendent of Mines, and under his authority Mr. Einar Lindemann made a survey of a portion of the field with the magnetometer, in whose use Mr. Lindemann was skilled. The Government of New Brunswick were also petitioned (under statutory regulations) for the use of the diamond drill belonging to the Province, which was granted, and the first hole was finished about the beginning of December, 1906, by which time Mr. Lindemann had completed his magnetometric survey and filed his report. Mr. Lindemann's opinion, as expressed in his report, was favorable to the existence of large bodies of ore, but could not, of course, indicate the purity or otherwise of such ore. For this reason the then owners decided to continue the work of drilling the field and obtaining analyses of the ore found in the cores.

(To be continued.)

BOOK REVIEWS.

A Text-book of Assaying, by C. and J. J. Beringer. 11th edition. Revised by J. J. Beringer. Crown 8 vo. Cloth, 10s. 6d. Charles Griffin & Co., London.

Is not the appreciation of high standards our higher education, and is it not to the Old World that we look for our standards? This book is one of the standards. It is one of that most excellent series of metallurgical books edited by the late Roberts-Austen. Published in 1889, it has now reached its 11th edition. One of its authors was at one time chief assayer to the Rio Tinto Copper Company. Its 11th edition has been revised by the Principal of the Camborne Mining School, a school that boasts, and rightly, of being one of the most practical mining schools in the world. Not only is it in the heart of a mining district but it owns a mine that is worked by the students. And because it is in an old district in which there are few openings for mining engineers these students are trained not specially in tin mining but for work all over the world.

This book certainly should be one of our high standards, not alone in assaying, but a standard for all technical works; it should be a standard in technical teaching; a guide not alone for students but for professors.

It contains 450 pages, sparsely illustrated, showing in its remarkable freedom from errors great care in its production. It has a fairly good index and an elaborate table of contents. The book is divided mainly into three parts, of which the first, covering only 86 pages, deals generally with methods, apparatus and reagents and more specifically with chemical equations and the determination of specific quantities. Part II. deals with the metals and alkali earths and covers 258 pages. Part III. deals with the non-metals in 90 pages, of which only two are given to coal. In all, the determination of 56 elements, besides cyanogen and ammonium, is outlined with greater or less elaborateness, and eight pages are devoted to the examination of water, including the determination of albuminoid ammonia. This sounds more like an encyclopedia than a text-book. In fact, it is somewhat of both. Gold, silver, and tin are dealt with fully. In copper and lead the treatment is not so complete. Iron from the ordinary assayer's point of view, not the iron specialist's, is fairly well taken care of, as are also manganese and sulphur. The rest of the determinations are touched on chiefly in outline.

All this is excellent; the general plan is good, but when we come to the details, alongside much that is good we find much of which to complain. As a rule the descriptions are clear, the effort is made to show each step distinctly, and the writers have generally in view an ignorant and untrained students; but the writing is often rambling and repeats itself, and does not leave the clear, succinct impression that is essential for laboratory work.

Proper weight is not given to methods and statements; several methods being given to accomplish the same end without any statement as to which is the best or sufficient explanation as to when one may be better than another. For example, the subject of the parting of gold and silver is dealt with in detail, eight pages geing devoted to it. The three methods of proceedure of parting in flashes, parting in test tubes, and parting in glazed crucibles, are given equal emphasis. From an academic point of view they are all three equally interesting; but from a commercial point of view, when one is working against time, they are not in the same class. This consideration is not even hinted at. Again, despite the eight pages of details of parting, we have to go back several pages to learn that it is not necessary to flatten out the bead before parting, that it may be done in the round form if sufficient silver is present, and nowhere are we told that if sufficiently dilute acid is used and the operation allowed to proceed slowly a coherent gold skeleton may result. This is a very simple point, but is sufficient to make or break the possibility of getting out the day's results.

This diffusing or scattering of the information occurs in other places, for example, in dealing with cupels. In Chapter II. on Methods of Assaying, in the description of apparatus there are a few lines on the making of cupels. In Chapter IX. under the heading of Gold there is some more information on the making of cupels. But in the whole book there is not enough information to teach a man how to make a satisfactory cupel. There is nothing about the desirable qualities of the bone ash or its necessary coarseness or fineness. There is not a word about the many cupel making machines in use at the present day, nor a hint at possible substitutes, such as Portland cement, that so many use with complete satisfaction. There are seventeen pages altogether on cupellation, and except for the lack of succinctness, they deal fairly thoroughly with the sub-

ject. The academic side is well handled, the practical or the commercial side does not seem to have occurred to the authors. And yet in other parts of the book detailed instructions are not lacking. We are told that coke furnaces should be started with wood, as the coke is hard to ignite. We are even told that when preparing samples "one ore should be done at a time." But these are minor details, only of importance as they shed light on the general trend of mind or method of the teachers.

On the all-important question of the choice of methods of proceedure the book is safe and solid. Except in the one case of tin it makes no effort to be up-to-date; it stands by the old reliable methods, and sometimes one is almost tempted to call it Archaic. One fails to find any attempt at quick methods or shortcuts. In fact, accuracy, and accuracy only, seems to be the qualification sought after. Time and simplicity of operation are so unimportant that one fails to find even a hint concerning them. The preliminary roasting of ores, sometimes in roasting dishes, sometimes in crucibles buried in coke (!) is recommended, and only once are nails referred to. It is true, it is sometimes recommended to use a bar of iron with sulphide ores, but we who never roast (or hardly ever), and to whom nails are as common in the assay office as crucibles, cannot help wondering at these methods.

There are, however, two good things in the way of methods. The authors condemn the pot or dry assay for lead. They say "it is only applicable to rich ores and with these only gives approximate results." They also damn the cyanide method for copper. This is good. They also in a great many cases show the effect on the accuracy of results of changes in the conditions of proceedure. This is often in the form of series of actual results. This is most excellent; it is the best point in the book, and one to which we would draw especial attention.

But though we have spoken well of their methods of determination, it must not be considered that even here their standards are such as we should look up to as high. They devote nearly six pages to the dry assay for copper. To the historian this method may be of interest, but why teach it to modern students? They say the electrolytic "is the most satisfactory method for copper," and they give eight pages to it, in which they describe old-fashioned apparatus, recommending the use of two cells of the old type Danniel battery, the porous pot of which "must be emptied out and recharged daily." They allow the current to act for sixteen hours and then say: "It still remains to determine any copper left undeposited in the solution," and they proceed to estimate this colorimetrically!

Now the electrolytic method for copper is not only the most useful that we have, but it is second to no other assay in accuracy of results, and it is less dependent on the skill of the assayer than any other assay. On the other hand, the colorimetric method depends entirely on the judgment of the assayer, and at best is only an approximation. To complete the electrolytic by the colorimetric is like doing most of a survey with a transit reading to minutes, and then finishing up with a prismatic compass; or perhaps a better simile would be to say that it was like making a journey in most part by automobile and then finishing up by walking the last few miles on foot. This may be all right and pleasant if one is an amateur and time is no object, but we learn assaying to earn money by it and we must get results. The electric current can be used to leave no measurable trace of copper in the solution, and even 10 years ago it did not take sixteen hours to do this. Nowadays it does not take four, and even on the weakest solutions the electrolytic method is much more accurate than the colorimetric.

However, as we have said before, the authors make not effort to be anywhere nearly up-to-date, except in the case of tin. In assaying cyanide solutions for gold they evaporate to dryness in a lead dish and make no mention of the zinc and lead acetate method. They always precipitate copper with sulphuretted hydrogen and make no hint of the possibilities of using aluminium. And their sulphuretted hydrogen they make in an ordinary bottle (upon which they waste one of their very few illustrations), that goes on making gas uninterruptedly till all the material is consumed!

Upon the whole question of apparatus they are very weak. They only mention two types of furnace, the wind furnace and the muffle furnace, both using coke. They illustrate these with the ash pit scorching the legs of the assayer. They mention no other fuel but coke, say nothing of gasoline furnaces, and never think of putting a crucible in a muffle, always using it in a bed of coke. They say that the fused material may be left in the crucible and "separated from it by breaking when cold." Also "wrought iron crucibles are very useful for making galena assays." And these statements, which appear to us foolish, carry as much emphasis in their book as their most valuable ones.

The whole subject of sieves is dismissed in three lines, and practically nothing is said about the degree of fineness to which a sample should be crushed, until they get to Appendix C, where there is a disappointing lecture on the theory of sampling. The only crushing appliance they mention is a "bruising-plate" which looks like our buck-board. It is used with a "bruising-hammer," which has a face four inches square! Not a word is said about any of the crushing or grinding machinery, which is so necessary to us. There is not even a word about the riffle-samplers of the Jones or other types, which we consider essential. They impress the importance of thorough mixing, but they give not one word as to how it may be done beyond laboriously forming the material into a cone. In fact, all the way through the book no evidence is given of the slightest appreciation of the value of time. Very little is said about balances, nothing about their care. It is not even mentioned that more than one kind may be required in an assay office. In fact the only specification in regard to balances is the unqualified statement that "a fairly good balance should be sensitive to 0.0001 gram." Of course everyday gold balances are sensitive to one-tenth of this.

But enough! Evidently this book, despite all pretentious environment of its birth, is not a standard, at least not a standard for us. What is the matter? It has several faults, but from the broadest view it has two main faults. It shows no sign of progress in the art. With the one exception of the chapter on tin, this book might have been written almost entirely 20 years ago. The second fault is that it is academic and not commercial. What is the cause of these faults? There are probably many causes, and we are not in a position to define them, but, with all deference, we must remember that the book was produced in Cornwall. Now the sum total of progress in mining in Cornwall divided by the number of years they have been mining there is less

than in most other spots on the globe. The Phoenicians mined in Cornwall. This must needs have its effect. Though this may be a reason, it should not be allowed as an excuse.

We have before us several medical books no more pretentious than this, and they all breathe the spirit of progress in every page. One in particular on miscroscopical work, which is comparable with our assaying, gives its best efforts to illustrating time-saving and effort-saving methods. The latest mechanical devices and the latest stains whose greatest claims lie in their ability to do more and better work in a given time are given precedence over everything else. Surely medicine is not less academic than mining.

This book is not a high standard—for us it is no standard at all. A student trained only in this book would not be able to carry on successfully even a small commercial assay office in this country, and unless he had a very kind chief could not rightly fill the position of assistant in a large one. It is a useful book for reference, there is much to be learned from it, but it is of a type of which the weak points must be recognized by both our students and our teachers.

H. E. T. HAULTAIN.

EXCHANGES.

Mining and Scientific Press, June 6, 1908.—The fourth of Mr. T. A. Rickard's articles on Goldfield appears in this number. Its subtitle is "Rich Ore and Its Moral Effects." The article is an instruction summary of "high grading" in a country where that nefarious art was carried to a high pitch of perfection. We shall transcribe a few paragraphs from the paper:

"Rich ore invites theft. Wherever men find minerals so valuable that a small weight of it represents money, there the temptation to steal is inevitable, the weakguard of conventional morality is broken, and the conscience of the miner is debanched . . . . 'High-grading' is larceny."

The peculiar labor conditions gave the labor union a dangerous control of the stock market. "Mining operations were condutced under leasehold; the owners of the mines were, for the most part, without experience of mining; they had no capital, and they did not know where to look for ore; so they granted leases to parties of working miners willing to work, and to adventurous operators willing to furnish the money for exploration."

"The ore was rich indeed. In the Francis Mohawk lease at a depth of 200 feet, there was eight inches of stuff that assayed $250,000 per ton; it was free gold and calaverite or telluride of gold. The various leases on the Mohawk mine yielded a total of $50,000 per day for 106 consecutive days. One carload shipped to the Selby smelter weighed 47 tons, and assayed 609 ounces of gold per ton, so that the shipment was worth $591,637, that is, more than $6 per pound. There were many places in the mines where men knew thy were breaking ore worth 10 to 15 dollars per pound. It was easy to steal several pounds of ore. And they did . . . It is estimated that last summer over $1,000,000 worth of ore of which no proper account was made went out from the Mohawk and Combination mines, and $500,000 to $750,000 from the Florence. Not less than $1,000 per day of illicit bullion passed trhougn the United States mint at Carson . . . . Only $300,000 was recovered last year from the whole camp, despite every effort to find the stolen ore. It is most difficult to trace the 'high grade,' for the thieves crush it at once and so destroy the chance to identify the poduct from any particular mine. Unless identified positively, the legal evidence is incomplete. The stolen ore is usually taken to a bogus assay office, the proprietor of which pays about 50 per cent. of its real worth. The ore is treated by chlorination . . . . In one case a plant was raided while in operation. The heading assayed 260 ounces gold per ton; the tailing assayed 15 ounces. Larceny does not wait on accurate metallurgical method."

The owner of the establishment said that "this residue would be sold to a man who intended to salt the oxidized ore on a neighboring claim. Even when the circumstantial evidence seems convincing, the local justices are afraid to convict; public opinion regards 'high grading' as rather humurous, the labor unions preach a doctrine by virtue of which a little rich ore is the miner's perquisite, the rush to become wealthy possesses everyone, and in the excitement the moral law is left high and dry."

"Regular harnesses were invented for carrying ore under the working clothes of the miners. They would step from the cage or bucket and stumble heavily laden on their way homeward without being arrested, although the officials knew why they walked so clumsily." Picturesque incidents are cited, especially of the connivance of the labor union. "And thus we come to the root of it all; the subservience of the lessees to the labor union. Why? Because the ore was rich, and the terms of the leases were short, the lessees could not afford to delay the extraction of ore by having trouble with the men; the men knew it, and so stole as much as they could . . . . The rights of property were not respected because the judges who preside over the local courts owed their position to political election."

But stealing was not confined to the miners. Stories are told of others, among them one of a mining company president who filled his suit case with specimen ore each time he visited the mine. His stealings in one year amounted to $22,000.

"During the strike that was ended in April, 1907, the stock market was worked by the labor union leaders. They would call a meeting under pretext of settling the strike, and the announcement of this fact would lead to the buying of shares by the general public; they would sell short, and then cover their shorts by open purchases made through their wives; this stimulated more buying; then the counting of votes cast at the meeting of the union would be dragged along so as to afford the time necessary to complete the stock transactions. Thus they see-sawed the market five or six times. This broke the brokers, who had been breaking the public. It was a merciless game of depredation. . . . There was not much to choose between them all; it was a case of catch as catch can, with the odds in favor of the one who first placed his hands on the ore—the miner himself."

The Mining World, June 20, 1908.—Henry A. Mather writes in this number of the mining and metallurgical industry in Georgia. The hydraulic gold of Georgia is generally so flaky that more than 50 per cent. escapes the riffles. When the sandy quartz veins are stamped and amalgamated less than 50 per cent. is saved. The mines generally credit the hydraulic dirt with $3 to the yard, though some of it showed over $100.

The deepest shaft in Georgia is 160 feet and the total gold extraction from 1825 to date is about $10,000,000, of which 80 per cent. has been obtained from hydraulic operations. No dredge has yet been operated in the country although dredging would probably be profitable.

Mining property is difficult to purchase at a fair valuation. Some of the older miners use blanket boxes as auxiliaries, to the rifles and there are reports of savings of over $60 per yard from the finer vegetable mold which necessarily churns up into silt and escapes the riffles.

The Colliery Guardian, June 12, 1908.—The Norton Hill Colliery accident is commented upon in the recent number of the Colliery Guardian. The investigation following the explosion brought out much conflicting evidence. The question as to whether the explosion was due to coaldust, to firedamp, or to both of these agencies, could hardly be settled. There is yet much difference of opinion amongst investigators. But "the official view that because some kinds of coaldust may produce an explosion, therefore all coaldust is to be regarded as dangerous, and precautions are to be taken accordingly, is without doubt the safest; but until there is more unanimity upon the coaldust theory, these precautions will not be taken in all cases, especially while any discretion is left to the management as to what is to be considered a dry and dusty mine."

PERSONAL AND GENERAL.

Mr. W. K. McNeil, manager of the Canadian Laboratories, Toronto, was united in marriage on June 17, to Miss Welsh of Markham, Ont.

Mr. J. J. Harpell, business manager of the "Canadian Mining Journal," is visiting Great Britain on business. He will be absent throughout July.

Mr. J. F. Black of Sudbury, Ont., visited Toronto on June 12. Mr. Black is the original discoverer of the Moose Mountain iron ore deposits.

Mr. S. Cohen, manager of the Crown Reserve mine, Cobalt, Ont., was injured recently in a runaway accident. Mr. Cohen's right shoulder was broken.

Mr. H. H. Sutherland, late of Haileybury, has returned from Rawhide. Since last February Mr. Sutherland has been working in that new camp. He has now secured an advantageous lease on a claim and is opening the property at a rapid rate.

Mr. W. Fleet Robertson, the provincial mineralogist of British Columbia, is exploring the Finlay River district. He will be absent two and a half or three months. He will examine the extent and value of the reported discoveries of placer gold at and around McConnel creek. On both trips Mr. Robertson will, by means of wide detours, explore the country. He will report upon the desirability and probable location of roads.

CORRESPONDENCE.

To the Editor,
"Canadian Mining Journal."

Dear Sir:—In your issue of June 1st, Mr. F. Hille makes some criticisms of two papers read by me before the Canadian Mining Institute, to which I desire to make a brief reply. Criticisms of such papers are welcomed by the Institute and by the writers, and if more written ones were made the Institute's Journal would gain in value. Such criticisms should, however, be of the facts given, or of the inferences drawn, and here Mr. Hille lamentably fails. To shorten this note I will not reply to his criticism of my paper on "The Iron Ores of Ontario," leaving that to Professor Leith, who is charged with the same error as myself.

As to my paper on "The Origin of Deposits of Pyrites" (Jour. Can. Min. Inst. X, 118-123, and Can. Min. Jour. Nov., 1907), Mr. Hille has done me the doubtful honor of reading it so carelessly as to be unacquainted with its contents. For instance, he says: "He attributes the origin of a large number of the pyrites deposits to sedimentation, and refers for support to Beck, Kemp and others." On the contrary, Beck and Kemp give no support whatever to my thesis, and I cited their two recent books on Ore Deposits to show current opinion on the topic.

Again Mr. Hille writes, "I fail to find any explanation as to what kind of sedimentation he ascribes their occurrence." Let me call his attention to the following quotations. "The third theory (sedimentary beds) assumes the precipitation of iron sulphide from solution as a bed at the bottom of shallow water. Other chemical and mechanical sediments occur above and below such beds." (page 1 pamphlet edition). "The pyrites in the iron ranges can be satisfactorily accounted for as a chemical precipitate" page 10. "We conclude, then, that for a number of our Ontario pyrites beds the origin has been one of chemical sedimentation" page 11, and further on pages 8, 9, and 10 details are given of how sedimentation was effected.

Again Mr. Hille says that I attribute to the pyrites deposits near Schreiber a sedimentary origin. On the contrary I wrote, "Near Schreiber. . . . . is a deposit of a different character," and specifically mentioned that "the ore is associated with an eruptive diabase, and is considerable mixed with pyrrhotite carrying small amounts of nickel and copper."

I can only acount for these mistakes by a very casual reading of my paper. There are other mistakes in his letter of a different class.

For example, Mr. Hille writes:

"There is no doubt that the Helen ore is to a large extent an oxidation product, from pyrites and siderite, but these minerals are not of the same age as the Animikie rocks, as has been repeatedly asserted, but date from the time of the greenstone eruptions, which occurred after the Animikie had been laid down."

I know of no competent geologists who asserts that these minerals are of the same age as the Animikie rocks. On the contrary such men as Van Hise, Leith, Coleman, Merriam and others agree in considering the pyrites and siderite of Keewatin age. Mr. Hille alone asserts that they are of post-Animikie age and we may reasonably ask for some proof of this amazing statement. I may note in passing that pebbles of pyrites and siderite from the Helen formation occur in the Lower Huronian conglomerate which much antedates the post-Animikie eruptive greenstones.

With Mr. Hille's suggestion that the "pond like places or rounded depressions are the collars and vents of craters, vents of geysers, or fumaroles" I have no sympathy. The pond at the Helen mine is undoubtedly due to solution (see paper by Coleman in Geol. Soc. Am.). At Goudreau Lake numerous examples are found of hollows from a few feet in diameter to several hundred. That they are due to solution has been admitted by all who have seen them.

Apparently Mr. Hille believes that the iron pyrites beds of Ontario are due to expiring vulcanism. If so, will he please explain why all these volcanic deposits happen to be associated with the Keewatin iron sediments? The Michipicoten pyrites for instance, he associates with post-Animikie greenstone. Why did these eruptions all occur for 60 miles along a narrow band of Keewatin iron sediments at most under 1,200 feet wide, and never in the Keewatin schists, or in the lower Huronian conglomerates and slates, or in the Laurentian granites which border this strip? How does he account for the microscopical character of these pyritous cherts which seem to all observers to be chemical sediments? Has he any evidence to offer that the pyrites was deposits in the siliceous and sideritic beds subsequently to their deposition as sediments? Criticism of this character would be valuable.

Yours truly,

A. B. WILLMOTT.

INDUSTRIAL SECTION.

The Manufacture of Grinding Wheels and Other Abrasive Products.—Before the invention of the electric furnace artificial abrasives suitable for grinding wheels were unknown. Wheel manufacturers necessarily depended upon natural products, chiefly corundum and emery. As emery occurs in considerable quantities in various parts of the world, it came to be recognized and used as the chief raw material for grinding wheels and other products employed in grinding metals. On this account the modern grinding wheel made of any abrasive is popularly known as the "emery wheel."

The Norton Company has during the past few years been operating an electric furnace plant at Niagara Falls, in which has been developed and brought out an abrasive known as alundum, which possesses the characteristics of sharpness, uniformity and right temper.

The introduction of alundum in the field of grinding has been remarkably successful and rapid. The requisites sought for and attained in this abrasive are extreme hardness and sharpness, combined with uniformity and proper temper. These qualities in alundum have had much to do with its successful development.

The process of making alundum consists in taking the purest amorphous oxide of aluminium found in nature, bauxite, purifying and melting it in immense electric furnaces, the power for which is furnished by the Falls of Niagara. Upon cooling, this molten mass solidifies in solid ingots of alundum. Beautiful crystals are found in the centre of these masses, showing nearly all the variety of colors found in the ruby and sapphire, of which alundum is one variety. The rarer col-

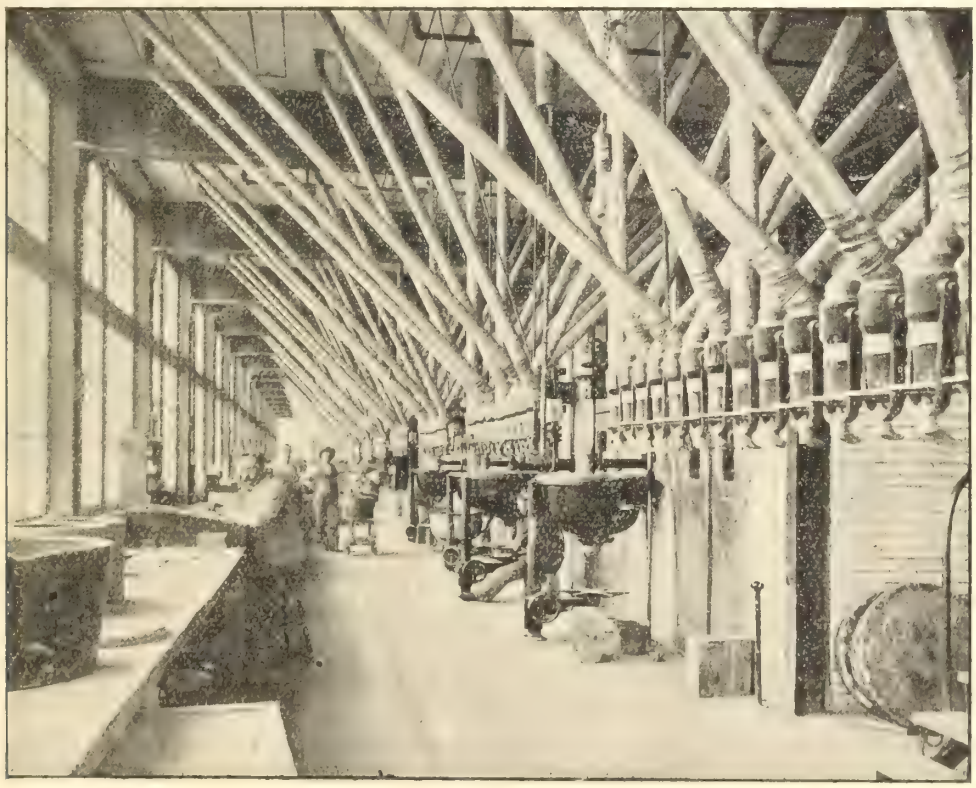

FIG. 3

ors of light pink, blue and purple found in Oriental gems are sometimes noticed in small crystals.

Bauxite is the purest naturally-occurring amorphous oxide of aluminium known. This mineral was originally found at Baux, France, from which it derives its name, but purer forms are now obtainable on this continent. The best quality only is used in the manufacture of alundum, and in its preparation practically all impurities are removed. The high grades of bauxite used are of rare occurrence. The Norton Company, however, owns its own mines from which the purest grade is obtained.

The bauxite is heated in calciners to drive off the combined water, and is then melted directly in electric furnaces of special design. It was not practical to fuse bauxite commercially until the invention of this process. The temperature in these furnaces probably ranges from 5,000 degrees to 6,000 degrees Fahrenheit.

The operation of these furnaces and the composition of the molten bath is under the control of the furnace operative. Exact quality and uniformity, which are so important in steel manufacture, are fully as important in the manufacture of alundum. The highest grades of steel are now being made in electric furnaces because impurities can be removed at the high temperatures obtained by the electric arc, and the quality of the molten bath uniformly maintained. In the alundum furnace both the purity and uniformity of the alundum are assured. Each step in the process is under the close supervision of expert chemists, who are constantly directing and following the work by careful analyses in the Norton Company's chemical laboratory.

After the ingots of alundum have cooled they are broken up and the pieces are then reduced to smaller pieces by means of powerful crushers. After this reduction the material is still further reduced by being passed through smaller crushers and several sets of grains, which are required in the manufacture of grinding wheels. After passing through rolls, it is subjected to the usual washing and drying processes to prepare it for manufacture into grinding wheels, rubbing and sharpening stones and other articles.

The solid massive alundum, while resembling the purest natural corundum in chemical composition, has the remarkable quality of being considerably harder than the natural product. This is due to the perfectly fluid condition in which the mass is brought, the control of its composition, the rate and method of its cooling and solidifying by which it receives its temper, and the absence of water of combination.

The necessary requisites for the most efficient abrasive for grinding wheels are: 1st, sharpness; 2nd, hardness; 3rd, right temper; 4th, uniformity.

In order to insure rapid and continued cutting so far as sharpness is concerned, a peculiar quality is necessary. There must be a fracture which will give a number of sharp cutting points.

In the matter of hardness the recognized standard is the diamond, which is the No. 10 in the scale of hardness; nothing that man has yet discovered or made equals the diamond in hardness. The term "hardness" is, therefore, a comparative term, the hardness of a mineral being ascertained by its ability to scratch another mineral of a known degree of hardness, or to be scratched by such a mineral.

Pure crystalline corundum, represented by the best sapphire or ruby, has always been the standard for No. 9 in the scale of hardness. This is readily scratched by alundum; in fact, alundum powder is used for cutting and drilling rubies and sapphires for watch jewels, etc.

By "temper" is meant its strength of grain and the character of its fracture under grinding pressures. An alundum grain is remarkably tough and will stand more crushing pressure before breaking than any other abrasive grain, but when it does break it breaks with a sharp crisp fracture, giving a fresh, keen cutting edge. This is a most important quality in an abrasive.

Purity, besides resulting in greater hardness and better temper, is necessary in the bonding of the grain into wheels in order to secure accurate and uniform results. Uniformity is necessary to secure constant efficiency of grade and temper in a wheel, so that wheels can be accurately duplicated at any time and maintain their standard of work.

Uniformity is one of the most important requisites in an abrasive. The ability to duplicate grinding wheels is essential to obtain the best results. In grinding wheels the abrasive grain of a given size is bonded together to produce a certain grade or temper for a certain kind of work. The term grade, as applied to wheels to designate the degree of hardness, is the resistance of the particles to the pressure employed in the act of grinding. A wheel from which the particles are easily broken is called soft, while one which retains its particles longer is called hard. Wheels are graded from soft to hard, depending upon the class of work on which they are used. Different grades of wheels are obtained, according to the amount of bond employed, the wheel becoming harder as the amount of bond used increases.

Different grades are required for different materials to be ground; cast iron, steel, brass, glass, bone, leather, wood and other substances demand wheels of special grade, which must be duplicated to make the grinding operation continuously efficient.

Then a record of each wheel is entered on a prepared form, with description on wheel, number of revolutions, order number, and for whom the wheel is intended. This record is signed and sworn to by the tester of the wheels each day before a Justice of the Peace, and carefully filed by the Norton Company. A record is preserved of each order, so that it can be duplicated exactly as to composition, cutting quality, shape and size.

Very few people realize the many uses for which grinding wheels are employed. They are used in the machine shop for sharpening all kinds of tools, cutters, reamers, taps, dies, etc. In the foundry for grinding castings. The sawyer gums and files his saws with an alundum wheel with no danger from drawing the temper of the tool. The leather manufacturer finishes the leather for suede gloves on a grinding wheel. The manufacturing optician grinds the edges of lenses for eye glasses. In the great glass works beading, fluting, edge grinding of tumblers, checkering fine stars, and fine work of all character calls for grinding wheels and abrasive stones.

The Canadian Fairbanks Company, Limited, are the selling agents for Norton grinding wheels, and stones and carry large stocks in their several warehouses at Montreal, Toronto, St. John, Winnipeg, Calgary and Vancouver. Catalogues and booklets describing the manufacturing of alundum into grinding wheels will be mailed to any address on application.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.

The management of the Nova Scotia Steel & Coal Company have not appointed their representative on the Board of Conciliation which was applied for by the P. W. A. upon this company's refusal of the men's demands for an increase in wages. The Nova Scotia Steel & Coal Company say they cannot afford to grant any increase in wages in the present state of the market, and their action in closing down their Sydney Mines steel plant should speak for itself, when considered in connection with the passing of the Scotia dividend. The fact of the matter is that the present state of the coal and iron market tends rather to a reduction in wages than any increases, and it was only the peculiar territorial conditions that attend the operations of the Dominion Coal Company that enabled that company to grant the increase they recently consented to under the Board of Conciliation held in March. It is evident that the Sydney Mines company cannot grant any advance in wages, and whether the leaders of the P. W. A. will have the courage to accept the inevitable, in the face of what will be urged against any such action by the fiery spirits who want to fight, remains to be seen. The fact of the matter is that the labor market is a shade too easy to warrant a strike in Cape Breton.

Mr. Graham Fraser's residence at North Sydney has been turned into what is now the Harbor View Hospital. The funds for the work of this much needed institution have been raised by the workmen of the Nova Scotia Steel & Coal Company, assisted by the company, and by a general public subscription at Sydney Mines. Everybody knows the crying need for proper hospital accomodation in colliery and steel towns, and the citizens and workmen of Sydney Mines are to be congratulated on their successful efforts in this direction.

The long agitated question of whether the P. W. A. shall amalgamate with the U. M. W. A. is to be decided by a general vote of all the members of the P. W. A. to be taken on the 24th of June and may the best men win. Like Josh Billings, we prefer to prophesy after the event.

So far the outputs of the Dominion Coal Company for the month of June have been remarkably good. To the 15th they aggregate 185,000 tons, and if all continues to go well the month of June, 1908, will be in every respect a record one. Indeed records are flying all over just now. All the mines from No. 1 to No. 12 are on the producing list, and new and old keeping up a steady average. In previous years June has shared with October the production of large outputs. The three summer months between are, however, fraught with uncertainty, it being the holiday and picnic season. Picnics are an institution dear to the heart of the Cape Bretonian, but they do not interfere dreadfully with outputs. We have often though it would be better if men would take their vacation in such a way as not to utterly disorganize everything at one time. It is a scheme that has worked well elsewhere. Every man is entitled to his yearly vacation, but one can understand the language of a colliery manager when his outputs go down and his costs go up, coincident with a picnic. Still, it is pleasant out o' doors in Cape Breton when the wild rose blooms.

One of the Halifax papers contained an article borrowed from English sources, having reference to the influence of a legislative Eight Hour day on the price of coal in that country, which classes as fallacious all arguments forecasting an increase in the price of coal following the enactment of an Eight Hour day, and proceeds as follows: "Poor men ask why they who work much longer than the miners, and receive far less than the miners, should pay more for a common necessity of life in order that the hours of a body of workmen much more fortunately placed should be still further reduced." This sentence is a gem of truth in the midst of a matrix of error, for the article goes on to insinuate that these same workingmen are being designedly stirred up against their fellows by the bogey of dear coal. But leaving this aside, we consider the question asked is a very natural one, and a question moreover that many, very many, British workingmen are asking themselves to-day. In conversing with an English emigrant recently the writer was told that the "British Workingman"—that favored person whose glorious possibilities and privileges are daily held up for the fatuous admiration of credulous workmen in this part of the Empire—was walking the streets of Sheffield, Manchester and other large manufacturing centres of England, thousands upon thousands of him, looking for work, asking nothing but work. This man expressed himself as being deeply grateful for the chance that had enabled him to leave his favored homeland to find a less favored spot where he could nevertheless find work and bread. He was a British workingman himself, but he expressed his views on radical legislation in terms that occasioned us some surprise, and led one to ask whether there were not many British workingmen who were thinking along similar lines, and whether the day was for distant when there would be a distinct revulsion against the present craze for class legislation gone mad.

Kipling, in one of his "Letters to the Family" properly arraigns the soi-disant British workingman in the following unvarnished way: "Englands' weakness is an excess of voters who propose to live at the expense of the State. They pride themselves an being an avowed and organized enemy of the Empire, which as others see it, waits only to give them health, prosperity and power beyond anything their votes could win them in England." The fact is the true spirit of labor, the spirit that has made England and her family over the seas, still survives in England, and the blatant demagogue who preaches political economy according to his lights over the beery table of the alehouse, is not the British workingman. There are, to quote Kipling again, "millions of silent careful folk accustomed even yet to provide for their own offspring, to bring them up in the resolute fear of God, and to desire no more than the reward of their own labors. . . . It is one of their preoccupations to send their children to Sunday school by roundabout roads, lest they should pick up abominable blasphemies." And Kipling sums up the matter thus: "Meantime the only serious enemy to the Empire, within and without, is that very Democracy which depends on the Empire for its proper comfort, and in whose behalf these things are urged."

We have digressed from the main point at issue. Our writer states that the price of coal will not be increased by an Eight Hours Act, and he goes even further than this, in the following remarkable statement: "It would be possible to produce and distribute coal at a much lower price than that now ruling, though the workers labored for even less than eight hours, and though the wages were even higher than the trades union standard." After stating that there will be no increase in the price of coal, he states that any increase which may after all take place is explained by the fact that the coal owners "might artificially raise the price of coal to direct public opinion against the Eight Hours Bill." We find it hard to see why the coal owner, who has to pay a higher wage for a less labor return, should need to resort to artificial methods of raising the price of coal. His cost sheets will go up quite naturally, and we think the only thing artificial will be the dividends. At the risk of being thought unprogressive we still think the capitalist is entitled to some return.

The article goes on to prove how small is the share of the miner in the price obtained for the coal, and gives the following figures, which may be taken as correct:

Cost of production per ton, including wages.....	5s.	6d.
Railway rates..	7s.	0d.
Cost of distribution to the consumer in London....	2s.	0d.
Wagon hire (car hire)	1s.	0d.
Contingencies....	1s.	0d.

We quote the comment: "From these figures it will be clear that the miners' wages are an almost negligible item in the cost of coal, and that if the swollen profits of the various grades of parasites could be eliminated coal would be sold at a much lower price." We wonder how much would satisfy the miner? We have hear this same kind of argument (?) put even more crudely than by the present exponent. Miners' leaders have been known to argue that if a miner received say 50 cents for his mining, and coal sold at $2.50, the difference between these two amounts was the profit of the coal owner. There does not seem to be much more in the argument above.

What then is the wonderful remedy for a state of affairs so disastrous to the poor miner? Nothing novel, but the same old gags, state owned mines is one panacea, another is mines owned and operated by co-operative societies. We are sagely informed that a combination of coal consumers would be able to "bid defiance to the mine owner, the railway magnate, the middleman, and all other exploiters who are at present busily engaged in playing off their victims one against another." Really! We once knew a co-operative coal mine in Lancashire, England. It dropped a good many thousand pounds of good co-operative funds before it was allowed to go to a rapacious capitalist. The management of that same mine was enough to make the angels weep. Co-operation is a good thing, in its place, but its place is very distinctly not in coal mining.

We remember also a certain trades union that bought a coal mine and operated it. However, it did not work, as the workmen asked for more wages, and had they continued as they began the defence fund would have disappeared altogether. It was a miners union by the way, and what they didn't know about mining was very little, so they said. It hurts a Yorkshire miner to be asked about this mine.

Quite what relation all these views on co-operation and state ownership have to do with the price of coal as affected by the Eight Hours Bill we fail to see, although the article is headed with a large title to this effect. It is on a par with other half digested views on economics that are being daily put before our workmen.

But what are the actual facts as regards the returns obtained by English capitalists in coal mining. According to the most accurate figures that can be obtained the earnings of the coal owners in the Northumberland coalfield taken over twenty-one years averaged 5 per cent., and allowing for redemption of capital, 3 per cent. on the money invested. It will be found that 5 per cent. interest represents about all the profit that can be legitimately looked for by a coal mining concern over an extended period. Sir Christopher Furness, than whom we know of no better authority, states that out of the money expended in raising coal, exclusive of reserves for depreciation and remuneration of capital, labor receives 75.8 per cent. as its share.

The following remarks are taken from the Colliery Manager's Pocket Book, and English publication that has been issued annually for 39 years:

"If coal mines, then, with their great risks, as an investment only yield upon an average the same interest as Consols, why do persons put money into them at all? The answer of course is that it is the chance of a large profit that tempts investors. If many lose their money altogether, some few make larger profits, and each one hopes to be one of the lucky few. Moreover, it is the lucky ones that are in evidence. They are necessarily men of ability as well as fortunate, because coal mining is by no means a mere matter of chance. The successful coal owner usually goes into parliament, makes a figure there, becomes a baronet, and may even rise to the dignity of becoming the subject of a cartoon in Punch. He comes prominently before the public, and gives a fictitious importance to the advantage of coal as an investment. The unsuccessful coal owner, on the other hand, disappears from the scene, and is quite unknown to the general public."

The following figures are taken from the returns of the English Board of Trade covering the period 1886 to 1900.

Tons drawn, 2,807,395,000.
Value at pits mouth, £953,477,000.
Average value per ton, 6s. 9.65d.
Expenditure on wages, £642,386,000.
Remaining over for expenses other than wages, £311,092,000.

The amount remaining over is thus distributed by Lord Joicey, whose figures are based on accurate facts:

		Per ton.
Wages..	£642,386,000	4s. 7.01d.
Rents..	75,904,000	6.50d.
Materials, etc.	157,646,000	1s. 1.50d.
Profit....	77,542,000	6.64d.
	£953,478,000	6s. 9.65d.

Applying these figures to Nova Scotian Coal mining, what do we find? The item of rents, which in the English coal owners' balance sheet bulks as largs as his profits and oftentimes larger, is represented in Nova Scotia by the Provincial royalty on coal. The cost of transportation by rail is paid to a Government owned railway. The cost of materials represents an expenditure without which many Canadian manufacturers would be. Are all these parasites?

Another person signing himself "Aberdeen" publishes an "Open Letter to the Workingmen of Cape Breton," in which these poor benighted beings are told a few of their hitherto unrecognized miseries. We take it that this same person is an Englishman, for his writing shows a detachment and a complete failure to recognize the genius of his neighbors in Cape Breton. He says that the Town of New Aberdeen, which we are informed is as large as any in Nova Scotia, is "literally covered by houses owned by the Dominion Coal Company," and that this town is Government property, which the representatives of the people have leased to the Coal Company for all eternity! We are further informed that the real owners, that is the workingmen, are unable to get an inch of it on which to build a dwelling or to do business. Evidently this gentleman never heard of the company's standing offer to build a house for any of their workmen, giving the lot at $25, at 6 per cent. interest on the building cost, giving more liberal terms to the purchaser than are to be found in any building society anywhere. The following clause in the company's lease may explain without further comment why the Coal Company have to be so careful with their leases: "The said land and any buildings thereon shall not be used in any event for the sale of intoxicating liquors, or for any illegal or immoral purposes." We are yet further told that the company's "shacks" are rented at $12 a month. Perhaps we may explain that these "shacks" are semi-detached blocks, each standing in a large lot. There are two houses in each block, which rent for $6 per month each. Each house has two large rooms and a kitchen downstairs, and three good sized bedrooms, opening on to a central hall upstairs. When one considers that in the Town of Glace Bay rents are as high as $15 for two rooms, and that it is impossible to get a house

equal to the Coal Company's houses at less than from $15 to $20 per month, it will be seen how dreadful the Coal Company's charges are. Further, this writer says the company's store is an oppression. Perhaps this gentleman will explain why the Coal Company have voluntarily closed five of their stores in two years. He says the Coal Company supply the miners with goods "after the goods are paid for, of course." The trouble is that so many persons objected to paying for their goods.

At the end of the letter "Aberdeen" says (in capital letters) that he is elated to think he is the son of a workingman. He would have reason to be ashamed were he not. We have no room for leisured gentlemen in Nova Scotia. But is not the cult of the workingman being overdone? There is a dignity in labor, but we protest against the modern limitation of the term "workingman" to a particular class, or the gratuitous assumption that no person labors but the "horny handed son of toil," which is the way in which the soft handed agitator usually refers to the man who is working out the primeval curse. We venture to assert that the grind of modern life, the relentless wear and tear of nerve and tissue, does not fall to-day upon the workingman—so-called. There are men who labor, although their hands may be white and soft, who would gladly exchange places with the manual laborer, men whose brains crave for the "sweet sleep of the laboring man." The laboring man has a vote, but it is not upon him there is laid the stress of government, the burden of empire, the guiding of great emprise. There are men who work sixteen hours a day: work, that is, not endeavoring to give the minimum return for the maximum remuneration, but the right of these men to the title of workingman would be denied by many whose hands are horny, but whose convolutions are few.

We further question very much whether in this Canada of opportunity, this the land of true democracy, there is any virtue in being a workingman, if such virtue consists only in working with hoe or shovel for a day's wage. The Canadian should be the lord, not the helot of his hand, and very often the claim to the distinction of being a workingman is the reward of incapacity, or a dislike to exertion, to put it mildly.

And we are so convinced that the average Canadian appreciates this view as to believe that it will be a long time before the insidious leaven which is at present permeating the working classes of Great Britain, and which threatens to reduce them to a host of state fed paupers as were the citizens of degenerate Rome, will begin to work in Canada.

Therefore we fear that the persons who write so luridly and so sympathetically about the woes of Canadian workingmen are weaving ropes of sand. Nova Scotian workmen, in particular, must be getting quite case-hardened to the heart stirring depictions of their parlous case that daily appear in their newspapers, and by this time they must be about as effective as sermons usually are.

ONTARIO.

Cobalt.

The rails have been laid as far as the Lawson mine on the Kerr Lake branch of the T. & N. O. R. R. The track will shortly be completed to the terminal at the Drummond mine. This will effect a very great saving in mining costs of some of the important shipping mines, and a large number of promising prospects. The Kerr Lake, the Drummond, Foster, Cobalt Central, Silver Leaf, Crown Reserve and Lawson will be able to load ore and unload coal and supplies from cars directly on the property. The Temiskaming, Badger, Beaver, Rochester, Shamrock and many others in this section will with the completion of the improvement of the wagon road also be in a much better position to get in supplies and ship ore.

The activity in the southeast section of the Cobalt camp, which resulted from the discovery of a good vein on the Shamrock, and the very satisfactory development of the Badger, has affected a large majority of the properties in this section. At the Rochester mine ten men are now employed and one drill in operation drifting at the 50-foot level, the management hope to be in a position to largely increase their working force in the near future. A small force of men has been employed trenching and stripping on the Cobalt Merger.

The shareholders of the Beaver Consolidated have authorisd the issue of 480,000 shares of stock to the shareholders of record for the purpose of providing funds for further development of the property. Twenty men are now employed, No. 1 shaft which is down 110 feet will be sunk to a depth of 200 feet and drifting started at this level.

At the Shamrock 22 men are now employed. The shaft is being sunk to a depth of 150 feet. It is the intention to cross cut to the vein recently located with a diamond drill. The foundation and buildings for the new plant are well under way.

On the Coleman development property cornering on the Temiskaming, a vein from five to six feet wide of calcite and quartz with smaltite galena and small silver values has been found. A test pit is being sunk on this vein and a drift started from the main shaft, on the No. 1 vein at the 100-foot level to strike the new vein. Thirty men are employed under the management of A. R. Webster. A new compressor has been installed and is now in operation.

The shaft on the Paterson property, which adjoins the Cobalt Development, is now down 70 feet and will be sunk to the 150-foot level.

A contract has been let to sink the shaft on the Progress to a depth of 100 feet and trenching will be started on several leads.

On the Wetlauffer property preparations are being made to start work at once.

Little Nipissing.—This company has leased the property of the Amalgamated Cobalt lying directly east of and adjoining the Trethewey mine.

The work on the Peterson Lake lease of this company is progressing very satisfactorily. The shaft is now down fifty feet. On June 9, a car of ore was shipped to Copper Cliffe, another will be shipped within a few weeks.

Cobalt Lake.—Mr. Justice Riddell has given judgment in the action of the Florence Mining Company vs. the Cobalt Lake Mining Company. The decision dismisses the action with costs from April 20, 1907, the date of the Act of Legislature confirming the title in the Cobalt Lake Company. Justice Riddell says in part: "It seems to me the only recourse for the plaintiffs is to appeal for consideration of the Lieutenant Governor in Council, with the manner in which such an appeal should be dealt with the Court has nothing to do."

Mr. Fraleck, the engineer in charge, in his recent report to the management states as follows:

"Re mining.—The north shaft is now down 139½ feet. At the 130 foot level a drift has been started towards the lake, a distance of twelve feet. The work for this machine for the past month comprises 21½ feet of sinking, 12 feet of drifting and in addition to this, the level station has been timbered.

No. 4, 1st level. The north cross cut is now in 318 feet from No. 3, or 421 feet from the drift on No. 4, making the driving for this machine duirng the month, 53 feet, and in addition this cut to the south is now in a distance of 360 feet, making the driving for his machine for the month, 70 feet.

2nd level. The north cross cut is now in a distance of 123 feet and the west drift is out underneath the lake a distance of 209 feet, making 63 feet of driving for this machine.

No. 6 shaft. This shaft has been sunk to a depth of 14 feet, with 45 feet of driving at the 138 foot level, making

three feet of sinking and 35 feet drifting for this machine, but in addition the level station and the bottom portion of the shaft has been timbered and planked during the month.

Our total footage for the month was 257½ feet.

Crown Reserve.—The foundations for the new plant have been completed and work started on the buildings. The plant will consist of a six drill Sullivan compressor, 100 h.p. Jenckes boiler, an Allis-Chalmers hoist, etc. A complete electric light plant will also be installed. It is expected that the plant will be in operation by July 15th. The working shaft will be sunk fifteen feet deeper to the 100-foot level and a cross cut run to the big vein.

City of Cobalt.—An option for 30 days has been given to an English syndicate. An engineer representing the syndicate is now examining the property. On June 10th, the directors declared a dividend of three per cent. with a two per cent. bonus payable July 10th.

Red Rock.—Drifting has been started at the 100-foot level. Twenty men are now employed.

Trinity Cobalt.—The compressor and boiler recently ordered have been delivered on the property and will be set up at once. The shaft which is being sunk on the shore of Cross Lake, is now down 25 feet.

T. & H. B.—Another dividend of $2 per share will be declared this month, making a total of $103 in dividends on every share.

Silver Cliff.—Dr. Beattie Nesbitt and associates have taken a working bond on this property, which lies directly north of the King Edward. Five machine drills are being run, power being obtained from the King Edward and Colonial.

Coniagas.—A thirty stamp battery with 1,250 pound stamps, is to be installed.

Montreal River District.

The recorder of this district, Mr. Thos. H. Torrance, received instructions on June 18th, to take immediate steps to move the office from Latchford to Elk Lake. Mr. Torrance will arrange for the construction of the necessary office building at once. This decision of the department is a very wise one and will be received with great satisfaction by the miners and prospectors in the various camps in the vicinity of Elk Lake. The mail service is so very unsatisfactory at all seasons and the difficulty of getting in to and out of this district in the winter months is so great that the necessity of going to Latchford, 52 miles away, to conduct all business in connection with the Recorder's Office or Department of Mines, has entailed a very considerable hardship on the prospectors. Under the present conditions it is also much more satisfactory for all parties concerned that the hearing of disputes and settlement of the many troublesome questions arising from under the Mines Act, be heard and decided on the ground. Elk City is beyond question the most central point for the seven or eight hundred men now in the district and is rapidly becoming a substantial town.

Semi-official announcement has been made that only one inspector has been assigned to this district and no inspection will be made except of disputed claims or at the request of the licensee.

Cobalt.

The flotation of the La Rose Merger has been the most important event, affecting the camp, that has happened for some time. It means the active development of properties of merit that have been lying idle for so long. It also means a greatly increased production from La Rose itself, where until now nothing but development work has been going on and ore taken out in that work is all that has been shipped. There is actually blocked out, a greater value in high grade ore, in this one mine, than the total capitalization of the Merger, namely $7,500,000. There is a large tonnage of low grade ore on the dump and blocked out in the mine, and undoubtedly a concentrator will soon be put up.

Crown Reserve.—A car of ore, 22 tons in weight, was shipped to Copper Cliff on the 5th inst. Taking the probable value of this car into consideration, about $135,000 worth of ore has been shipped to date.

T. & H. B.—On the 8th of June a dividend of $2 per share was paid. This brings the dividends paid per share to $101. There are about 7,700 shares issued, the capitalization being $25,000.

Century.—A small force which is to be increased very shortly, is at work here sinking a shaft. The shaft is down 84 feet and a contract has been let to sink an additional 40 feet. A boiler hoist and pump have been installed.

Temagami Reserve.—An option has been given on the Stirling mine at Arsenic Lake near Temagami. Work will be started at once. The ore deposits are big, comparatively low grade ones. The ores are copper-gold bearing mispickel. Five leads have been opened up. From a cut on one of the mispickel leads, 100 tons have been taken, now on the dump, that will average 30 per cent. arsenic and $12 in gold and silver.

ALBERTA.

Lethbridge.

The past few weeks have seen some very heavy rains in this district. These rains have been welcomed by the farmers as assuring them a bountiful crop in the fall. Miners and all classes of the community have likewise appreciated the rain as good crops mean good business for the West and good business means good coal trade. However, the rains have not been an unmixed blessing, as all the mountain streams are in heavy flood and considerable damage has been done to bridges, etc. The Belly river overflowed its banks and did a great amount of damage, all the "flats" being flooded.

The Alberta Railway & Irrigation Company have considerable mine workings lying under these "flats" and in some cases where pillars were drawn the caves had gone right up to the surface. It was foreseen some time ago that should these "flats" be flooded the water would find its way into the mine, and in anticipation of this several dams had been built. As expected the water soon began to flow into the mine when the river overflowed, and had it not been for these dams confining the water to one district, the whole mine would have been flooded.

It is the intention of the company to pump out this water as soon as additional pumping machinery can be laid down. It is supposed that it will take several months to finally free the workings from water.

The mines are only working two and three days per week, but is is reported that better time may be made in the near future.

Bankhead.

Mr. John Galvin, vice president of District No. 18, U. M. W. of A., has been negotiating with the management of the Bankhead Mines Limited, with a view to setting a contract price on pillar drawing in No. 5 seam. Mr. Galvin and the Local Committee met the management but failed to come to an agreement and the question has been referred to the Disputes Board for settlement. This board meets in the middle of each month to decide all cases which cannot be settled direct at the mines.

At present the pillars are being taken out by day labor, the rate of wages being the union rate of $3 per day, and the management claim that the contract price the men are asking would mean a wage very much in excess of this.

BRITISH COLUMBIA.

Michel.

The dispute between the Crow's Nest Pass Coal Company and its employees has been settled at a meeting between the district officers of the union and the management. The men who were discharged, have been reinstated, while the case of the employment of Henry Marchant, over whose non-employment the trouble started, has been dropped.

It now appears that Marchant is not a union man and the union therefore refuse to further his case. The action of the secretary of the Michel Local union is being strongly condemned on every hand, and it is the opinion of the district officers that every greivance of the Michel miners could have been settled without losing a single day's work.

Rossland.

On the Surprise and You Know portion of the Le Roi Two property an active campaign of development work by diamond drilling is in progress. The surface showing on these claims is very promising and the management are of the opinion that the time has arrived to further prospect these indications of ore. The output of the Le Roi No. 2, Limited, for May was 2,410 tons and some of the ore gave an average assay of 3.77 ounces gold and 6.7 per cent copper, making it worth $88.80 per ton. The lode in which these values were found was of an average width of two feet and another vein of an average width of four feet one inch carried 2.82 oz. gold and 9.7 per cent. copper, equal to $79.68 per ton.

In the lower levels of the Le Roi mine encouraging results are being obtained and once more the affairs of this concern are brightening. It is expected that the gross receipts from the operation of the mine during May will equal those of April, if they do not exceed them, and as the April receipts were $90,000 if those for May are greater it will tend to show that things are getting better with the big mine, and that the results of the campaign of extensive development work carried on last year are about to be realized.

The shipments for the week ending June 6th, and for the year to date, from Rossland camp show the following tonnage shipped:

	Week.	Year.
Centre Star	3,860	76,971
Le Roi	1,610	37,349
Le Roi No. 2, Limited	385	11,919
Giant California	....	95
Blue Bird	....	110
Red Eagle	....	20
Evening Star	....	428
Total	5,855	126,892

Work is going on in a busy manner around the small properties of the camp and a busy and profitable summer is looked forward to.

Phoenix.

The shipments from this district for the week ending June 6th, amounted to 25,807 tons, of which the Granby shipped 18,051 and the B. C. Copper Company properties 7,756 tons. This runs up the total amount of the Boundary for the year to date to 478,244 tons.

The information that the Granby Company had declared dividend of two per cent. payable June 13th, on their outstanding stock was welcome news to the many shareholders throughout this section and also to the business interests here generally. This act augurs well for the season's work that now lies before the Boundary miners. There will be no child's play in the winning of dividends from Mother Earth's stores of gold and copper in that section, but the sharpest and most far-seeing minds will have to use their best efforts to bring about this much desired result, owing to the low price of copper and the other difficulties to be contended with.

This is dividend number nine to be paid by the Granby since 1903, they having divided profits in these nine dividends with their stockholders to the sum of $3,238,630, this, of course, including the dividend now declared and about to be paid. Up to date the Boundary mines have paid $3,806,776 in dividends; the B. C. Copper Company having paid $201,200; Cariboo-McKinney, $546,837; Consolidated Company of Canada, $781,885, and the Providence $38,224, in addition to the above named sum distributed by the Granby.

Work at the B. C. Copper Company smelter has been started since last writing and the plant is now handling about 1,950 tons of ore daily. During the week ending June 13th, this smelter treated 12,215 tons. The Granby smelter for the same week treated 19,030 tons of ore, the ore shipments averaging about the same as for the week mentioned above. Four cars of blister copper were sent away from the B. C. Copper Company's smelter during this last week, and the new Rand duplex compressor which will be one of the largest and most up to date machines in the country, is expected to be making air within a few days now. One of the prime features of this machine is that it cuts out automatically to only 75, 50 or 25 per cent. of its capacity (3474 cubic feet) and consequently only consumes a proportional amount of power; making no more air than is being used. The compressor is driven by a 600 h.p. motor—rope drive.

The total ore shipments from the Granby for May totaled 93,316 tons, which is the greatest quantity ever shipped from the mines, with the exception of March. While all of the smelters furnace equipment was in operation in March, however, two of the furnaces were out of commission most of the time during May. For the first five months of this year the Granby shipments are 294,317 tons, a third more than for the same period last year, which is a pretty good showing under existing circumstances.

Events are so shaping themselves that work will be started on the Dominion Copper Company interests here in the near future. Preliminary statements to this effect have been received with gratification here. It is expected that the final word will be given shortly after the convention of the company's officials at Salt Lake City.

The Phoenix M. S. & D. Company recently formed has added another promising claim to its list of properties. Work on the E. P. U. is being steadily executed and in the course of the work this week at a point 900 feet in the tunnel another stringer was cut which gave an assay of $145.

A one quarter interest in the Ajax and all of the Munster claim are to be sold at auction to satisfy a judgment obtained by F. M. Kerby against the McKinley Mines, Limited, for $406.80.

Nelson.

At the Queen Victoria mine, on which there is one of the largest showings of low grade copper ore in this district, a careful sampling of the property has been made and a 100-ton lot shipped to the Northport smelter for a test. Work has been resumed on the Buffalo, under management of Bruce White. The controlling interest in the Buffalo is held by Spokane mining men who are determined to give close attention to development work on the property. A mine that was a shipper from the Slocan twenty years ago, the Alpha, is once more being worked and the near future may see this old timer once again on the shipping list.

The Free Silver group, on Quartz Creek, is to be developed

extensively this coming season. There is a promising showing of galena on the group and the men behind the scheme are of sterling character.

Now that it is a forgone conclusion that the lead bounty will be extended for another five years, from June 30th, and with the two or three improved features which it will embody, the lead miners of the Slocan are already lying back with a sigh of relief, assured that for this further period they will be assured of a stable minimum price on the product of their mines.

GENERAL MINING NEWS.

NOVA SCOTIA.

Sydney Mines.—The closing of the iron and steel departments of the Nova Scotia Steel & Coal Company will reduce the output of the company's collieries by several hundred tons per day. The rumours of labor difficulties have been greatly exaggerated. The suspension of active work in the iron and steel departments is due to the fact that heavy stocks are now on hand.

The closing of the company's open hearth and blast furnace plants mean the throwing out of about 800 men engaged in these departments, with a pay roll of about $40,000 to $50,000 per month.

This does not take into consideration the effect this closing of the steel plants may have on the output of the mines.

The amount of coal consumed at the blast furnaces and open hearth is 600 tons per day, which represents the output of about 200 men engaged directly and indirectly in the handling and mining of this amount of coal.

The company have now this additional 600 tons of coal per day to find a market for.

Sydney Mines.—The new mine, Sydney No. 4, of the Nova Scotia Steel Company, commenced to be a producer on a promising scale on the first of the month. The management made no attempts at an output until everything was in readiness for a good start. The output for the first week of operation was expected to be 400 tons per day, and this ought to be doubled as soon as another machine is installed.

The company's coal shipments for May and the five months were as follows:

Shipments, May 1908	67,758
Shipments, May 1907	43,348
Increase, May 1908	24,410
Shipments, 5 months, 1908	223,495
Shipments, 5 months 1907	163,627
Increase, 5 months 1908	59,868

Sydney.—Three steamers are expected by the Dominion Steel Company to load rails for lake points for the Canadian Pacific, Canadian Northern and National Transcontinental Railways. Each of these vessels will carry 6,000 tons of finished steel. Arrangements have been made by the Steel Company to load twelve steamers with rails during the next two months, all of which will be shipped to lake points. American engineers, presumably of the Hill system, are at Winnipeg watching the results after the Cape Breton rails have been placed, and should they prove satisfactory, it is the intention to place several large orders with the Dominion Steel Company. The local plant is running twenty-four hours, with every skilled laborer available in harness.

Sydney.—The Dominion Iron & Steel Company has purchased half the property known as the Carlins Farm in the vicinity of the company's blast furnaces. It is believed that the object of the purchase is to allow the company latitude to ultimately increase its blast furnaces equipment.

Glace Bay.—From figures secured it is found that 810 of the Dominion Coal Company employees were off duty on Monday following pay day—that is, 10 per cent. of the total number employed. There were no picnics or other attractions to cause this.

The company figures that they lose at least 130,000 tons of coal per year by men absenting themselves from work.

The loss in wages to the men is $130,000; to the Government in royalty, $16,250, besides the value of the coal and the company's profit. This staying off work costs Cape Breton half a million dollars annually. Lay-offs are due largely to picnics and pay days.

ONTARIO.

Cobalt.—The Chambers-Ferland property, which is the basis of latest flotation on the Toronto and New York exchanges, comprises 124 acres adjacent to the La Rose, Nipissing, O'Brien, and Right of Way. It is under the same penalty as the O'Brien—the necessity of paying a royalty of 25 per cent. to the Ontario Government. Messrs. Frank Loring, M.E., and J. Edwards Leckie reported on the mine for the promoter, C. J. McCuaig of Montreal. The capitalization is $2,500,000 with but $300,000 in the treasury.

Port Arthur.—The Beaver Superior mill is being equipped. Twelve months' supply of ore is said to be stoped out.

ALBERTA.

Coleman.—More coke ovens are to be built at the works of the International Coal & Coke Company. The number at present in commission is 200. This is to be doubled. Materials are already assembled and ground has been broken.

BRITISH COLUMBIA.

Hazelton.—Returning prospectors from the Dighy river gold fields bring many contradictory reports. A few facts, however, are to be accepted on their face. Prospectors may choose one of two trails, the Omenica and the N. W. M. Police trail. On the latter trail the Skeena has to be crossed twice. Pack horses must swim the current and packs are taken over in boats. On the Omenica trail there is only one small stream to ford. A trail is being blazed to Bear Lake. Supplies are scarce and horses are difficult to obtain.

Phoenix.—Official notice was received early in June that the mines and smelters of the Dominion Copper Company would resume work on June 15th, and instructions were forwarded to get everything into shape. The interest on $8[illegible] of 6 per cent. bonds has been settled. All the machinery is in good condition. At the Boundary Falls smelter sufficient fuel in stock to last for a month. There is also seven days' ore supply there in the bins. The Rawhide mine, with its enlarged trackage will be able to output 1,000 tons per day.

Vancouver.—The Ikeda mines, on Ikeda Bay, Moresby Island, send now about two hundred tons of ore per month to the Ladysmith smelter. This ore is won largely by development work. A four drill compressor has been installed and

larger shipments will hereafter be made. A figure of 2,000 tons per month is expeteed. The hand sorted ore carries 12 per cent. copper, $5 gold, and sixty ounces silver per ton. A dump of 1,000 tons second grade ore carries 8 per cent. copper and slightly less gold and silver than the first grade. Eighty-seven men are employed. Four tunnels open up the ore-body. The vein varies in size from five feet of high grade ore to eleven feet of low grade. Ore bunkers are being built.

YUKON.

Dawson.—The claim in 38 below Hunker, mostly unworked ground and supposed to be very valuable, was relocated by three Dawson citizens on May 19th. The Guggenheim dredge No. 7 is working immediately above this claim.

Dawson City.—Dave Cunningham, a miner working on No. 3a, below Discovery on Last Chance, made a brave rescue recently. A young Slav was overcome by gas whilst working in a shaft on the claim. His partner deserted him; Cunningham hurried down the shaft, made fast a rope about the unconscious man, and, after reaching the surface, worked for three hours in resuscitating the victim. His efforts were successful. Cunningham's bravery was the sensation of the day.

The Bear Creek dredge, the pioneer large machine on the Klondike river, is running in good form. The ladder has been lengthened seven feet and new buckets have replaced the old.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The general report relating to mines and quarries for 1907 shows a total output of coal for the United Kingdom amounting to 267,830,962 tons, as compared with 251,067,628 tons in 1906. The production of iron ore was 15,731,604 tons, as compared with 15,500,406. The total number of persons employed in or about the mines was 972,220. At the mines under the Coal Mines Ast there were 1,245 deaths by accident, an increase of 29. The mines under the Metalliferous Mines Act had 34 fatalities, and there were 89 deaths by accident in the quarries, being a slight decrease in both cases.

A committee of coal owners in the Swansea districts has been formed for the establishment of a central rescue station at Swansea for the training of men in rescue work.

The Conselt Iron Company, of Newcastle-on-Tyne, has associated with a number of British, German, French and Belgian iron manufacturers to open up iron ore deposits in Algeria, where mining experts report a large quantity of ore of good quality about 100 miles inland from the port of Bona.

NORWAY.

The government has granted a concession for the Rustvangen mines in Hedemarken, to the Pehrson & Dovre Company for 75 years, the property to revert at the end of that period to the State without compensation. Only Norwegians are to be employed, and all material must be bought in Norway so long as it is not 10 per cent. dearer than that obtainable abroad.

RUSSIA.

A rich find of gold has been made in the lands of the Avriano-Petrovoski works of Orenburg province and development work has been begun.

Near the village of Biacly Klyutch, in Tiflis district, large deposits of manganese ore have been discovered by prospectors. The metal content is given as over 65 per cent.

UNITED STATES.

A new mining camp in Nevada, situated near Cactus Springs, 22 miles east of Goldfield, and within 15 miles of the San Pedro Railroad, has been christened "Rockefeller."

The United States Steel Corporation has taken over the iron ore properties of the W. L. Le Rue and Robert Whiteside of Duluth, in the Baraboo district, Wisconsin, and is preparing to undertake the development of mines. The only shipping property yet developed in this field is the Illinois mine of the International Harvester Company.

In May the two mines of the Butte district, Montana, produced about 27,537,300 pounds of copper from 346,425 tons of ore.

The consolidation of a number of producing zinc mines in Wisconsin is being negotiated at Benton with the object of erecting a joint ore-separating plant of the galena roast type.

MEXICO.

The new smelter of the Douglas Copper Company at Fundicion, Sonora, has been blown in and is expected to be an important factor in the development of mining ore on the west coast of Mexico. Hitherto all ore had to be shipped in the crude state to distant points for shipment. The smelter was mainly constructed to treat ore from the company's neighboring mines, and so far only the first unit of the plant has been installed, but with the development of theindustry it is expected that outside supplies will be extensively purchased.

The Benito Juarez Company has received machinery for its 150-ton mill and cyanide plant at Penon Blanco, San Luis Potosi. The plant will have a battery of 1,050 stamps and there will be 23 steel cyanide tanks for sand and slime treatment.

The Cananea Consolidated Copper Company has been granted a concession by the Mexican government for prospecting for oil in the State of Sonoro. The company will use oil in place of coal in its operations.

AUSTRALASIA.

There are nearly 1,000 miners at the Oaks Rush, Queensland where gold has been found at various points over an area extending for three miles. At the Three Nobs rich stone is being obtained at a depth of 30 feet.

A large deposit of iron ore is being opened up about six miles north of Mudgee Township near Lowes Peak, New South Wales. Two hundred tons have been sent to Lithgow for treatment and of the bulk sample proves equal to former tests an important industry will be established.

The lack of a sufficient water supply threatens to cause the closing down of the Great Cobar copper mine, New South Wales, employing 960 men.

In the Hill End country, New South Wales, quicksilver has been discovered in two places a mile apart.

SOUTH AFRICA.

Further substantial reductions in Rand working cost were made in April last. In the eight mines of the Eckstein Central Administration group, the average cost per ton milled was cut down to 17s. ¾d. The Robinson company records working

costs for the same month as 12s. 9-8d., as compared with 13s. in March.

What is claimed to be a world's record in underground driving has been made by two men employed on the Simmer Deep property, who carried a drive 24 feet in 61 consecutive shifts of 10 hours each. The size of the drive was 5 feet by 7 feet. One white man and six Chinese were employed on each shift, and they operated three Ingersoll-Sergeant rock drills on a bar.

CHINA.

The East Chinese Railway Company has for some years been working several coal mines in the Usswri district of Manchuria, and has recently started to work on two new coal deposits not far from the Lihmienpo and Harbin stations. The total requirement of coal for the road will bes upplied by these mines in future, and the company has organized a special department for their management.

STATISTICS AND RETURNS.

Outputs of Dominion Coal Company, June 1st to 15th, 1908.

No. 1	28,280
No. 2	34,980

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp and those from Jan. 1st to date:.

	Week end. June 13.	Since Jan. 1.
Coniagas	63,100	568,680
Kerr Lake	57,980	462,300
McKinley	123,600	1,497,160
Nova Scotia	43,990	271,545
Little Nipissing	40,110	40,110
O'Brien	276,330	2,817,300
Right of Way	61,050	303,290
Temiskaming & H. B.	65,000	664,000
Trethewey	67,600	1,065,056

The total shipments for the week were 878,760 pounds, or 439 tons. The total shipment from Jan. 1st to date are 15,874, 508 pounds, or 7,937 tons.

The output of the collieries of the Crow's Nest Pass Coal Company for the week ended June 12 totalled 22,769 tons, a daily average of 3,795 tons.

Following are the weekly shipments from Cobalt camp, and those from January 1st to date:

	Week end. June 20.	Since Jan. 1.
Buffalo		653,710
Coniagas		568,680
Cobalt Lake		246,455
Crown Reserve		84,000
Cobalt Central*		156,380
City of Cobalt		452,110
Drummond		148,000
Foster		238,400
Kerr Lake		462,300
King Edward		127,240
La Rose	104,670	2,486,322
McKinley	60,000	1,557,160
Nipissing	239,880	1,982,000
Nova Scotia		271,545
Little Nipissing		40,110
Nancy Helen		140,429
O'Brien	128,120	2,945,420
Right of Way		303,290
Provincial		144,210
Silver Leaf		196,620
Silver Cliff		52,000
Silver Queen		634,510
Townsite		85,100
Temiskaming & H. B.		664,000
Temiskaming		325,000
Trethewey	65,670	1,130,726
Watts		246,020

The total shipments for the week were 598,340 pounds, or 299 tons. The total shipments from January 1st to date are 16,533,118 pounds, or 8,266 tons.

*Concentrates.

Cobalt's output shows a big increase over last year. The tonnage of the first five months of 1908 is 2,649 tons more than that of the corresponding period of 1907.

The following monthly table shows the shipments of the camp for the first five months of the years 1907 and 1908:

	1907.	1908.	Inc.
January	908	1,325	345
February	993	1,173	279
March	1,027	1,832	805
May	1,158	1,601	443
April	533	1,317	784

Total shipments for five months, 1907, 4,662 tons; 1908, 7,257 tons; increase, 2,649 tons.

British Columbia ore shipments for week ending June 6th:

The shipments from the mines and the receipts at the smelters of the districts of South-eastern British Columbia for the past week and year to date were:

Ore Shipments.

	Week.	Year.

The output of the Crow's Nest Pass Coal collieries for the week ending June 19 was 24,273 tons; daily average of 4,047 tons.

Following are the figures of German consumption of foreign coper for the months, January to April, 1908:

	Tons.
Imports of copper	56,533
Exports of copper	2,723
Consumption of copper	53,810

as compared with consumption during the same period in 1907, of 36,225 tons.

Of the above quantity 52,259 tons were imported from the United States.

Reported by L. Vogelstein & Company, New York.

Production of Coal in United States for 1907.

In the year 1907, coal production in the United States reached high water mark. The increase in production over 1906 was 66,292,764 short tons, or 16.01 per cent. in quantity, and $101,751,749 or 19.83 per cent. in value. The following table gives the quantity and value of the coal production in the United States in 1907, by States:

State.	Quantity (short tons.)	Value.
Alabama	14,250,454	$18,405,468
Arkansas	2,670,438	4,473,693
California and Alaska	24,089	91,813
Colorado	10,790,236	15,079,449
Georgia	362,401	449,686
Idaho	a7,588	a31,119
Illinois	51,317,146	54,687,382
Indiana	13,985,713	15,114,300
Iowa	7,574,322	12,258,012
Kansas	7,322,449	11,159,698
Kentucky	10,753,124	11,405,038
Maryland	5,532,628	6,623,697
Michigan	2,035,858	3,660,833
Missouri	3,906,294	6,399,616
Montana	2,016,857	3,907,082
New Mexico	2,628,959	3,832,128
North Dakota	347,760	560,199
Ohio	32,142,419	35,324,128
Oklahoma (Ind. T.)	3,642,658	7,433,914
Oregon	70,981	166,304
Pennsylvaia:		
Anthracite	85,604,312	163,584,056
Bituminous	150,321,437	155,837,770

Virginia	4,710,895	4,807,533
Washington	3,680,532	7,679,801
West Virginia	48,091,583	47,846,630
Wyoming	6,252,990	9,732,668
Total	480,450,042	614,831,549

a. Includes production of Nebraska and Nevada.

Great Britain's production of coal in 1907 was 267, 828, 276 long tons, or 299,969,669 short tons, and Great Britain is the second coal producing country of the world. The coal production of the United States in 1907 exceeded by 180,480,373 short tons, or more than 60 per cent. that of the British Isles. It was more than double that of Germany, and was equal to 40 per cent. of the total coal production of the world.

COMPANY NOTES.

The Crown Reserve Mining Company, Limited, has declared a half yearly dividend of four per cent. for the current year ending June 30,being at the rate of eight per cent. per annum. The dividend is payable only to shareholders of record on June 15th.

The directors of the Nova Scotia Steel & Coal Company on June 13th declared the usual dividend of two per cent. on the preferred stock payable July 15th, to shareholders of record June 30th. The transfer books will be closed from July 1st to 5th, inclusive. The directors decided not to pay any dividend on the comon stock for the quarter ending June 30th.

The annual meeting of the Dominion Iron & Steel Company will be held on June 25, and the annual statement to be presented then was made public in Montreal to-day. The company's fiscal year ended May 31st, and it is pointed out that the earnings of the company have again to be considered in the light of the judgment against the Dominion Coal Company. In the previous year, all the coal used has been charged against

operations at the contract price of $1.28 per ton. Interest charges for the year amounted to $696,814, and the net earnings were $1,917,011. From this there has been transferred to contingent account $1,376,831 to offset the sum which has been charged to the Dominion Coal Company for money paid during the year in excess of contract prices for coal. The remainder has provided for the sinking fund on first mortgage bonds, and maturing instalment of second mortgage bonds, leaving a balance of $220,417. Gross earnings were $2,613,815, compared with $2,247,566 for the preceding year. The output of steel was 280,00 tons, against 255,500 last year.

The directors of the Kerr Lake Mining Company on June 9th declared their eleventh regular quarterly dividend of two per cent and a bonus of one per cent. on the capital stock of the company, payable July 1st, 1908.

The Temiskaming Mining Company on June 18th declared a dividend of three per cent. on the par value of each share issued, payable July 1st, 1908.

The City of Cobalt Mining Company has declared a dividend of three per cent., with a bonus of two per cent., payable on July 1st, 1908.

Dominion Steel Company's Claims.

The Steel Company's claim of damages against the Coal Company is as follows up to May 31:

Paid for extra cost of coal purchased from Dominion Coal Company	$1,847,550.18
Paid for extra cost of coal purchased from others	465,005.76
Damages due to short deliveries in August, September and October, 1906	132,252.75
Damages due to cessation of deliveries in November, 1906, estimated	479,000.00
	$2,923,808.69

The interest to the same date amounted to over $80,000.

MARKET REPORTS.

Basic, $16.15 to $16.40.
Malleable, $15.90 to $16.40.
Southern No. 2, $16.40 to $16.90.

Other Metals.

June 22—

Tin, Straits, 27.95 cents.
Copper, prime lake, 13 cents.
Lake, arsenical brands, 12.9 cents.
Electrolytic copper, 12.9 cents.
Sheet copper, 17 cents.
Copper wire, 14.75 cents.
Lead, 4.55 cents.
Spelter, 4.60 cents.
Sheet zinc, 7.50 cents.
Antimony, Cookson's, 8.60 to 8.65 cents.
Aluminium, 33 to 35 cents.
Nickel, 45 to 47 cents.
Platinum, $21 to $24 per ounce.
Bismuth, $1.75 per pound.
Quicksilver, $43.50 per 75 pound flask.

Silver Prices.

	New York. Cents.	London. Pence.
June 8	52⅞	24⅜
June 9	53	24 7-16
June 10	53⅛	24½
June 11	53⅜	24⅝
June 12	53⅜	24⅝
June 13	53⅜	24⅝
June 15	54	24⅞
June 16	53⅞	24⅞
June 17	53⅞	24⅞
June 18	54⅛	25 1-16
June 19	54⅛	25⅛
June 20	54¼	25 1-16
June 22	54½	25⅛
June 23	55⅛	25⅜

The first five months of 1908 show a decrease of £1,746,488 in silver shipments from London to the East as compared with 1907.

MARKET NOTES.

An advance of a dollar a ton in iron bars is predicted early in July. A large volume of business was booked in the first week of June in iron and steel bars.

The following table shows the present prices of certain classes of steel under the revised schedule, compared with a year ago:

	June 19 1908.	1907.
Bessemer iron	$16.50	$24.55
Bessemer billets	23.00	30.00
Plates	1.60	1.70
Structural steel	1.60	1.70
Wire nails	1.95	2.00
Iron bars	1.40	1.75
Steel bars	1.40	1.60
Sheets	2.40	2.50
Tin plates	3.89	4.00
Steel rails	28.00	28.00

It is estimated that the annual production of copper in the United States and Canada totals 1,000,000,000 pounds. The cost, making no allowance for depreciation, sinking funds, etc., is as follows:

250,000,000 lbs. ore produced at a cost of less than 10c per lb.
500,000,000 lbs. ore produced at a cost of about 12½c per lb.
250,000,000 lbs. ore produced at a cost of about or over 15c per lb.

The average cost of production is just about the present selling price.

Late in the week ending June 6th, Corrigan, McKinney & Company made a cut of 50 cents per ton on iron ore.

Machinery for Sale at a Bargain

1 Corlis Engine, 16" x 36", with separate condenser. In good condition. Completely overhauled six months ago.

1 Internally Fired Scotch Boiler, about 86" dia. x 18' 0" long. Two furnaces, 33" dia. x 6' 0" long. 136 tubes, 10' 0" long, 3" dia., about 200 H.P.

2 30 K.W., 110-v. D.C. Generators, 800 r.p.m., multipolar, compound wound, complete with pulleys. In excellent condition.

1 60 K.W., 250-v. D.C. Generator, 700 r.p.m., 6-pole compound wound. This machine is also in first-class condition.

1 Duplex Pump (Worthington), 9" x 5¼" x 10". In good condition.

1 Pump (Union Steam Pump Co.), steam cylinder, 5 1/8" dia., 3 5/8" stroke. Pump cylinder 8" dia.

2 Six-ton, 19-ft. Jib Cranes (steel frame). In good condition.

1 5-ton, 17-ft. Jib Crane (steel frame), in good condition.

1 Portable Key-way Slotter (Morton Mfg. Co.). In first-class condition, scarcely used.
Also some lathes, shapers, &c.

All the above have been in use until recently and can be put into service immediately. They will be sold either singly or "en bloc." Apply to THE CANADIAN LOCOMOTIVE COMPANY, LIMITED, KINGSTON, ONT.

Amatite ROOFING

Amatite has one distinction which makes it stand out above all others. *It has a real mineral surface.*

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather, the great durability.

This mineral surface is embodied in a layer of Pitch, *the greatest known waterproofing material.* Beneath this in turn are two layers of the best grade of wool felt—cemented together by more Pitch, making the whole a roofing that is *absolutely waterproof.*

No other ready roofing can compare with this mineral-surfaced, waterproof, weatherproof, durable roof. *Don't buy your roofing until you have seen Amatite.*

FREE SAMPLE AND BOOKLET

Send for Free Booklet and Sample to-day It will pay you to get acquainted with Amatite. Address nearest offine.

POSITION WANTED BY MINING ENGINEER

Twenty years' practical experience on Lake Superior, also among the complex ore mines of the West, filling positions from clerk to general manager. Can show remarkable record for reduction of costs, etc. Highest indorsements. Can go anywhere. Will accept any reasonable offer. Age 40; married; strictly temperate. Address, H. F. E., c/o CANADIAN MINING JOURNAL.

MINERALS
and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLAR

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

ROOF RIGHT NOW

There is one roof that saves money because it will last 100 years. Guaranteed in writing for 25 years.

"OSHAWA" GALVANIZED STEEL SHINGLES

This roof saves you work because its so easy to put on (do it yourself with a hammer and snips), and save you worry because they fireproof, windproof and weather-proof the building they cover. Write us about it and hear all about 207 ROOFING RIGHT. Address

The PEDLAR People (Est'd 1861).

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St. Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

BRITISH COLUMBIA

The Mineral Province of Canada

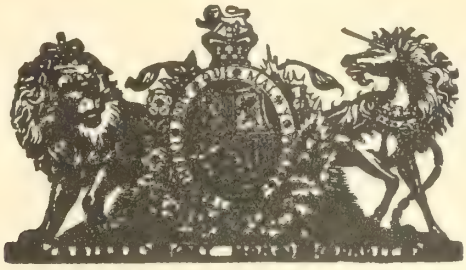
has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.



Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

Class WB-2 Air Compressor

Sullivan Air Plants For Coal Mines

SULLIVAN "CLASS WB-2" Air Compressors are especially suited to coal mining work, by reason of their high air efficiency, substantial design, and excellence of construction. They will run for long periods, without undue wear or delays, and require but little attention. (Catalog 658.)

SULLIVAN HIGH PRESSURE Compressors, of the Corliss, 4-stage type, are particularly economical as a source of power for pneumatic locomotives.

SULLIVAN PICK MACHINES owe their wide reputation for high cutting speed and ease of manipulation to their positive valve motion, a feature used only in this "puncher." From 1,300 to 1,600 tons of coal have been mined in twelve shifts, with one of these machines, in regular work. (Catalog 657 explains the advantages of machine mining as compared with hand pick mining and with solid shooting.

RAND AIR COMPRESSORS

EFFICIENT AND ECONOMICAL

Complicated mechanism in air compressor design is regarded as an element of weakness and it is the elimination of such non-essentials that has produced the up-to-date RAND Machine; a machine which operates with the minimum of attention and repairs.

Our Catalogs describe Rand Compressor Construction.

CANADIAN RAND COMPANY LIMITED

The JEFFREY
26-B "SHORTWALL"
ELECTRIC COAL CUTTER

For room and pillar work on the Longwall plan.

It cuts faster, consumes less power per cubic inch of coal cut, occupies less space, permitting the props to be set closer to the face of the coal,

is more easily controlled, operated and handled, is simpler and has greater strength, motor power and endurance

than any other make of
SIDE CUTTING MACHINE.

This machine is loaded' unloaded, moved to and from the coal face and in fact handled throughout by its own power.

FULLY DESCRIBED IN BULLETIN No. 14

COAL AND STEEL.

The president and directors of the Dominion Iron & Steel Company, at the recent annual meeting in Montreal, decided to reject the offer made by the Dominion Coal Company. That offer appeared to us reasonable and generous. In the event of the Dominion Coal Company winning before the Privy Council the Steel Company was to receive $1,250,000.

If the Steel Company won, $2,000,000 would be put in its coffers. The future price of slack coal was fixed at $1.50 per ton and run-of-mine at $1.80.

There is little need of reviewing the history of the struggle between these corporations. Until lately hope of a peaceful settlement has not been abandoned. Popular sympathy was undoubtedly with the Dominion Iron & Steel Company during the first stages of the conflict. Its decisive victories over its formidable antagonist were looked upon by not a few as being in accordance with justice. But in our opinion, there has been a dangerous element of sentimentality in the attitude of the public; and this attitude has not been without its influence upon the decision of the courts.

However, regarding all but the immediate past as a closed book, the fact obtrudes itself that all advances have come from the Dominion Coal Company. Its recent offer of a compromise stands in remarkable contrast to its attitude when the trouble first arose. We do not doubt that its directors, in consenting to make such a proposal to their opponent, have disregarded their personal animus and have sacrificed the interests of their own corporation to an extent that indicates an honest desire for peace. Therefore we mark with regret a certain resolute hostility that characterizes the utterances of the President of the Dominion Iron & Steel Company. The time for this has passed. On both sides sacrifices must be made. A sweeping legal victory for either side might easily resolve itself into an industrial catastrophe.

We have yet to learn what reasonable concession Dominion Steel is willing to make. So far the concessions have come from one side only.

UNFINISHED BUSINESS.

Last March at its annual meeting in Ottawa, two topics of especial importance were discussed by the Canadian Mining Institute, and two resolutions, embodying the sense of the Institute, were passed unanimously.

The former of these resolutions had to do with methods of collecting mining statistics.

The collection of mining statistics is, in itself, beset with many complications and hindrances. There is no law compelling mining or smelting companies to make sworn returns to the statistician of the Federal Department of Mines and that official must rely upon the courtesy of his correspondents.

Operators are under legal obligation, however, to furnish all necessary returns to provincial authorities. At first glance it might be concluded that this is sufficient for all purposes. Such, however, is far from being the case.

For instance, each province has its own method of computing the value of mineral outputs and each differs from the plan followed at Ottawa. Moreover the schedule of questions varies in each case. To add to the difficulties that confound the Dominion statistician, whose task of co-ordinating and standardizing would be a heavy one at best, provincial returns are further complicated by the fact that the official year is not identical in each province. Hence, complete returns are obtained only with disproportionate labor and worry.

The desirability of establishing uniform systems both of evaluation of raw materials, and intermediate and finished products, and also of an agreement whereby throughout the several provinces and at Ottawa, returns may be had in their entirety at the end of the calendar year, needs no argument. At present the apparent discrepancies between provincial and federal statistics is a source of confusion. The Canadian Mining Institute has taken the matter up. It has recommended "that a conference be arranged between the Deputy Minister of Mines and the Deputy Ministers of the Provincial Bureaus to devise, if possible, an uniform method of compiling statistics and valuing mineral products."

The matter must not rest here. By passing the above resolution the Institute recognized officially the need of reform. It has put its hand to the plow and there will be loss of dignity and prestige in failure to carry the movement to a sucessful conclusion.

Another subject, quite different in its bearing from that touched on above, but of at least equal interest, was brought before the Institute by Mr. J. B. Tyrrell. Mr. Tyrrell's resolution, seconded by Dr. T. L. Walker, read as follows: "Resolved—that the Canadian Mining Institute ask the various railways in Canada to issue tickets to prospectors at reduced rates, similar to the tickets now sold to home seekers; the records of such tickets to be endorsed on the Miners' Licenses held by such prospectors." This met the full and hearty approval of the Institute and was passed unanimously. It is a well-conceived and practical means of assisting prospectors, and, hence, a definite step towards opening up new mineral territory.

It is not easy to conceive of two more useful directions of activity for the Canadian Mining Institute than those outlined. Why then is no further action being taken? If the Institute is to fulfil its high mission, if it is to justify the liberal assistance heretofore granted it by Federal and Porvincial Governments, it must accomplish more than mere resolutions. To this end active committees are needed to co-operate with the secretary and council. And, were the members of these committees selected carefully, we have no doubt that the objects of both resolutions would be attained in a surprisingly short time.

CORRELATION OF INTERNATIONAL STRATA.

Mr. Horace F. Evans has recently contributed two articles to the Mining World of Chicago, on the subject of the correlation of international strata. Mr. Evans' treatment of his theme is popular. He sketches the work performed by the International Committee and assumes a judicial attitude in summing up results. By implication and by direct statement he asserts that the Canadian Geological Survey has neglected paleontologic investigation of the older strata of Southern British Columbia. The prediction is made that "exact correlations" of these strata will be accomplished by United States geologists in Northern Washington. "The paleontologist and the paleobotanist cannot expect to find much favor with colonial governments that have 'millions for tribute' but only a few thousands for economic science!"

It is evident from all this (and more that we have neither the time nor the patience to quote) that Mr. Evans has failed to fortify himself with facts. Nor is he conversant with the range and the character of the labors of the Canadian Survey.

The distinguished heads of the Canadian Survey had clear and correct conceptions of correlation. At present the Survey is co-operating with the United States geologists. In British Columbia work was begun long before that country was penetrated by a railway. Ever since that time paleontologic research has been carried on and each year has seen an increasing volume performed.

Dr. Dawson's first efforts were entirely confined to reconnaisance. He then chose certain districts for detailed examination. Where fossils were found successful correlation resulted. In disturbed regions, where the search for fossils was unsuccessful, final correlation was naturally impossible.

Of late the Survey has paid especial attention to the mining districts. Organic remains are not found here. But the investigation of the geologic phenomena of these regions is of prime importance to the province. No one, for instance, can deny the benefits accruing to the mining industry from the Survey's efforts in the Boundary district. But, since fossils are not to be found, why send a paleontologist to search for them? Mr. Evans' position is not sweetly reasonable.

On the other hand the Canadian Survey has seized with avidity any evidence of fossil-bearing strata in British Columbia and has in all cases dispatched paleontologists to hunt and collect over promising ground.

Mr. Evans aspersion on the "Colonial" (meaning "Canadian") Government is torrid atmosphere. The Canadian Geological Survey should, doubtless, be more liberally supported.

But, in proportion to their respective mineral industries, Canada appropriates just three times as much money as does the United States. Moreover, although working on a smaller scale, the Canadian Geological Survey has done incomparably more towards the correlation of international and western strata than has the United States Survey with its large staff and its heavy appropriations. Mr. Evans can hardly ask for more than this. Meanwhile we must thank him for giving us an opportunity to blow our own "National" horn.

DISCOVERY BEFORE LOCATION.

Dr. Raymond's vigorous article in our issue of June 15th has evoked much comment. On another page we print a communication from Mr. W. T. Newman, who concurs almost wholly with Dr. Raymond's position. Mr. Newman condemns the Ontario system of claim inspection as being apt to "lead to grave abuse" and as "an interference of a paternal nature with the search by the public for mineral wealth." He concludes that the vital point is uniformity—one law applying equally to all locations and covering essential revenue and a definite amount of actual exploratory work to be performed annually. Beyond that Mr. Newman's only plea is "let us alone."

It will be appropriate now to hear some voices from Cobalt and beyond. We shall welcome letters from our readers in the bush—from the men who are "up against it."

STANDARDIZATION.

A month ago we reprinted, for the benefit of our readers, the question-forms circulated by the Institution of Mining and Metallurgy. We have been encouraged by a letter from the Secretary of the Institution to urge Canadian mining men to submit answers to these question.

We wish again to request that our readers go carefully over these schedules and send us their opinions for publication. In our next issue we shall publish one set of answers already received.

Standardization is a particularly live and important topic, and it is both courteous and liberal on the part of the Institution of Mining and Metallurgy to offer non-members an opportunity of expressing their opinions.

THE MINING AND METALLURGICAL SOCIETY OF AMERICA.

As the result of vigorous canvassing, discussion and argument, the Mining and Metallurgical Society of America has been launched. Amongst its 114 charter members are many of the most distinguished engineers, metallurgists and geologists on the continent. On the printed list only two Canadian names appear, and these are the only foreign addresses included. Hence the new society is hardly cosmopolitan in its present scope.

That useful body, the American Institute of Mining Engineers, has long been regarded as meeting all the requirements of the mining fraternity. But it has been recognized that the Institute is incapable of performing certain necessary functions. For instance, it cannot take any part in watching and controlling legislation. Nor does membership imply technical attainments or professional standing. But the American Institute of Mining Engineers has exercised a wholesome and uplifting influence upon the mining fraternity of its own and other countries.

Yet more remains to be done. The Mining and Metallurgical Society of America is a strictly professional society. Membership in its is limited to the ranks of the mining and metallurgical engineers, and mining geologists. Whilst a high standard of professional ability and personal character will be insisted upon, yet membership is understood not to be an unqualified endorsement.

One proposal is to print brief records of the professional careers of each member. This thoroughly radical step will no doubt has a beneficent effect.

The five principal fields of activity are briefly as follows:

1. The establishment of local sections, meeting probably once a month, to promote good-fellowship among the members and to exchange views respecting technical and professional matters.

2. The determination of standards in engineering practice, such as is being done by the Institution of Mining and Metallurgy. This is considered a most profitable field of work.

3. The discussion of questions relating to professional practice and ethics, with a view to the gradual formulation of rules for guidance, determined by the concensus of opinion in the Society.

4. The discussion of questions of public policy in which the profession of mining engineering is directly concerned.

5. It is intended that the Mining and Metallurgical Society of America shall be a strictly professional society, etc., etc. This section we have touched upon already.

It will be in the directions defined in sections 3, and 4, that the distinctive work of the new society will lie.

In neither direction will there be serious overlapping of the field honorably occupied by the American Institute of Mining Engineers. In fact, to be useful at all, the Mining and Metallurgical Society of America must avoid duplicating the functions of its older sister. Another and less obvious danger lies in the abuses of power that characterize all close corporations.

Canadian mining men will watch with interest the growth of this fledgling. Meanwhile it is satisfactory to reflect that our own Canadian Mining Institute, whatever its deficiencies, has won its spurs. Its scope is wide enough, and its character sufficiently flexible to enable it to adjust itself to whatever contingencies arise. However, the time may soon be ripe for classification and segregation of its heterogeneous membership. When this is accomplished, Canadians will have the advantage of combining in one society all the advantageous features that mark its several sister organizations.

Editorial Notes.

The Mexican Mining Journal announces that Mr. Kirby Thomas, of Denver, Colo., for some years associate editor of the Mining World has taken full charge of the editorial management of the Journal. Mr. Thomas edited the two special Mexican editions of the Mining World. He is thoroughly familiar with Mexican mining and is well fitted to assume the editorship of our bright contemporary.

The Minister of Finance has given notice of a resolution that will have an important bearing upon the production of petroleum from bituminous shales. It is proposed to provide a bounty of one-half cent per imperial gallon on crude petroleum produced from shales or other substances mined in Canada. This places these products in the same category as petroleum obtained from flowing wells.

DISCOVERY BEFORE LOCATION.

Written for "The Canadian Mining Journal" by W. Thos. Newman.

[Editor's Note.—The following typographical errors occured in Dr. Raymond's article on the subject of "Discovery Before Location." We take this opportunity of making the necessary corrections, so that all ambiguity may be cleared away. Mr. Newman's contribution to the discussion presents a British Columbia point of view.

The errors referred to in Dr. Raymond's paper are:

1. First column of article, third line, the word "solid" should be "valid."
2. Same column, fifteenth line form bottom, the word "location" should be "locators."
3. Second column, third line from bottom of first paragraph, "land" should be "lands."
4. Second column, second line of second paragraph, "indefeasable" should be "indefeasible."
5. Second column, eighth line from bottom, "If he could sell it" should be "If he could not sell it."]

Answering your request for further discussion of the above subject, after reading Dr. Raymond's interesting paper in the last edition of the "Journal," I would remark:

The actual discovery of mineral of commercial value if properly conditioned should be the "sine qua non" of the granting to an individual a portion of the public domain, as it undoubtedly is the one and only inducement for the exploitation of the same and its conversion from a useless portion to one of both public and private value. This is I consider a demonstrable proposition, and therefore the "modus operandi" is the real question at issue. It is acknowledged by all of the men with whom my mining business in British Columbia brings me in contact, that British Columbia titles to lode mining ground are the best in their experience. If the supreme test be that of validity then the very few law suits over titles in this province compared with other countries would seem good evidence of the fact. Clause "28" of the "Mineral Act" quoted below, may also be useful to any seeker after information on the subject of land titles. It is worthy of some thought and reads: "Upon any dispute as to the title of any mineral claim no irregularity happening previous to the date of record of the last certificate of work shall affect the title thereto, and it shall be assumed that up to that date the title to such claim was perfect, except upon suit by the Attorney-General based upon fruad." It is especially significant that there is no precedent for a suit by the Attorney-General under this clause. British Columbia mining titles are absolutely secure.

In, I think, 1898, the writer was on a committee appointed at the request of the Government to suggest any possible alterations to the Mineral Act, and one of the two or three ideas suggested bears very closely on the matter under review. This was "that all applicants for a record of a mineral location should be required to bring into the recorder's office two fair cabinet size samples of the mineral found at his discovery post and make affidavit that the samples were found "in situ' at that point." One of these samples properly labelled was to remain in the local office and the other to be placed in the Museum at Victoria in the Department of Mines. It would seem that such provision should for all time settle the fact of actual discovery or non-discovery on such location. Also the Government would, as pointed out, in a few years have a collection costing nothing, every sample sworn to have come from a given location, and containing such a collection, as it would be impossible to get together in any other manner. Given the above addition to the present mode of staking mineral loca-

tions in British Columbia and the present law would appear about as perfect as it could be made. The Ontario method of having an inspection made by a government official, whether competent or not, is bound to lead to grave abuse and is an interference of a paternal nature with the search by the public for mineral wealth which will not attract the best class of prospectors to what is undoubtedly a rich field and one where the natural difficulties are unusually great, constituting quite sufficient handicap to the individual prospector who is the real explorer and on whom the province must perforce rely, if the "back of beyond" is to become the real producer of wealth in that great country. The last recommendation in that committee's report was "let us alone" and this to-day is perhaps the greatest need of most countries where adequate mining laws are in force. It is true that there are some countries on this continent still which have never had any real mining laws. With arguments in the able paper quoted by Dr. Raymond other than the doubt as to "bona fide" discovery being a good thing, I am in full accord. Allow any man or men to take up just as many claims as the annual assessment is faithfully performed upon and no more, and both the prospector and the capitalist will have ample opportunity to secure whatever they may deem desirable. The one point is—uniformity. Have one law applying equally to all locations covering essential revenue and a certain amount of real exploring of the ground annually and then "let us alone."

VALUATION OF MINING PROPERTIES.

By George H. Gillespie, M.E.

The valuation of mining properties for operation and profit earning should always be looked upon from a commercial point of view. The engineer or valuer must, therefore, always keep before him this question: If I buy this mining propery for a given price, spend a certain sum on plant, development and equipment, will the probable output from this mine return such expenditures, plus a reasonable return on capital so expended, commensurate with the risk undergone?

It is not claimed or expected that all mining properties can or should be purchased as certainties. The purchase price of a speculative venture should surely, however, bear some reasonable relation to the possible profit to be earned from successful operation.

Great stress is often laid upon the phenomenal success resulting from the operation of certain properties, properties that at earlier stages may have shown or (more correctly) it may have been claimed that they showed little or no evidence of their great productive future. It is again often claimed, usually by interested parties, that many good properties have been turned down by the trained valuer, which later on made good. It is certain that the trained and experienced observer does make mistakes, but it is equally certain that he makes fewer mistakes than the untrained man.

The critic of the trained mining valuer, when he cites the case of the mine that made good after it had been turned down by the valuer, usually omits to mention, and is often ignorant of, the reasons on which the opinion had been based. It may be that the property was worth a price, but not the price at which it was open for consideration. Many reasons might be given to show why a property turned down at one time might later on, under changed conditions, become valuable.

The problems of mine valuation may be divided roughly into two classes: (1) Mining prospects on which no work of determinative ore blocking has been done, butw ork of a merely indicative nature. (2) Mining properties on which actual ore reserves have been blocked out, the ideal case being a mine which has a past, a present, and a future, viz., past production, actual present operation, and the certainty of future profitable or positive ore reserves.

The valuation of the first class of mining properties is attended by a great deal of risk. The risk may be minimized by comparison with similar conditions, known to exist elsewhere. Should the prospect be situated in a district that has had large development of similar claims, great aid may be derived from a consideration of conditions found at various stages of development in such claims, and comparison with conditions at similar stages found in the prospect to be valued. That is, the study of the mining history of any given district should prove of positive assistance to the valuer.

The highest probable value of any mining prospect in a given district may be approximately stated to be the average value of successes in that district, successes being taken to mean such mines as may have been actually worked as paying propositions. Exceptions will, of course, be found to a general rule such as this. Mines vary in value, as do other things. There will always be the best and the worst mine. However, as a basis of valuation a rule such as this should prove valuable. If a district is a new one, or an old district in which little or no great success has been met with in actual practice, even should indications on a given claim appear to be exceptional, a small valuation would be justified.

The valuer must be willing to take a fair risk, his duty being to look for merit and business opportunity, not simply to condemn.

The valuation of producing mining properties is the problem that comes more nearly into the province of true engineering. In a producing mine data can be collected which when correlated should give a foundation for actual calculation of values.

I shall divide producing properties into two classes, based upon the nature of the valuable contents of the ores: (1) Ore values that are not subject to market fluctuations, such as gold. (2) Ore values that are subject to market fluctuations, such as silver, copper, lead, etc.

It must be manifest that a property whose payable probabilities are based on ores of metals whose selling price fluctuates over a wide range must be valued on the average probable price of such metals during a reasonable assumed lifetime of the property.

The engineer is therefore called upon not merely to value from a geological standpoint, but he must consider the commercial and metallurgical factors. By his knowledge of geological and mining conditions, he

can arrive at his estimate of the lifetime of the mine, and by his commercial and metallurgical knowledge at the value of the mine.

He must be able to estimate the ore actually in sight by the usual methods of sampling, and he should be able to cost the ore through to the market. The value of an ore to a mining company is that profit, if any, that can be earned from mining and treating the ore, and marketing the product of these operations.

The question confronting the mine valuer or buyer is the usual commercial one faced by the buyer of dry goods or other merchandise: What is the fair price to me, that is the price at which I can buy, operate, and make a profit? And mining differs from no other business in that the object of conducting mining operations is the earning of profit. If the initial mistake of paying too much for the property is made, then the venture is foredoomed to failure. A mine has an absolute value. It may be difficult to determine that value at the early stages of operation; but the value is, however, absolute, no matter how obscured.

The ore reserves in mines other than gold mines, that had been valued on market values of a year ago, would, on the same ore reserves be to-day worth as a result of market fluctuations about 20 per cent. less. In addition to this direct result of the falling prices of metals, a mine's value is affected in another way. The falling prices of metals mean that the market is less able to buy, and that a mine will therefore probably be forced to reduce materially its output on account of the inability of the market to take care of such output.

Should the financial condition of the mine warrant it, during low markets, to prevent over-production of metals, it might well be that the cheapest storage of metal is in the stopes of the mines as unbroken ore. Initial over-capitalization and over-valuation may force production and operation at periods of low-priced metals, when it had been better policy to have temporarily suspended or reduced operations. A mine really contains just so many ounces, pounds, or tons of valuable contents, and when these are sold at low figures there is just so much less to sell at the high figures. In largely developed mines production averages may be maintained by working low grade ores during high priced metal markets, and high grade ores during low priced markets.

The valuer of a mine is faced with that distinctive feature of mining, the fact that the miner destroys his assets to earn his profits. Each ton of ore produced is one ton nearer the working out of the mine, and a ton that cannot be replaced. That is, in a given area there is a certain quantity of ore—that, and no more. Therefore capital investment must be based upon the return of this capital in the period of time in which this ore body will be exhausted. Dividends from a mine are rarely income, but must be looked upon as being income plus redemption of capital. The lifetime of a mine is therefore an important factor of mine valuation.

The costing of mining operations for valuation of ore reserves can only be done by a man familiar with actual mining operations. The cost per ton is often stated as a figure that looks reasonable. If one takes the result of a year's operation on a mining property, multiplies the tonnage by the tabulated costs per ton, and subtracts the product from the gross value of the ouput, the result would appear to be the profit per ton. However, the actual net profits are very different, and are always much less. One is therefore forced to the conclusion that the actual cost per ton is the difference between actual profits and gross value of the ore, and that tabulated results obtained from many cost systems are merely book-keeping. In my opinion the only true basis for tabulating comparative costs for valuation of ore reserves is the cost of production of unit in values in the ore, say the ounce for gold and silver taken as refined, or the pound for copper, the total cost per unit being the actual cost to market, the profit per unit being that profit earned after total cost has been deducted.

The advance of the cost per unit of value as against cost per ton of crude may be illustrated in the valuing of gold mines. I will take the case of small vein as against a large ore body.

I will suppose that the character of ore in both cases is similar. Costs stated are arbitrary, but the ratio of operative costs is fair.

Small vein, 2 feet, 1 oz. per ton gold values.
Large vein, 30 feet, $3 per ton gold values.
1 ton, 2 foot vein = 1 oz.
7 tons, 30 foot vein = 1 oz.
Cost per ton, 2 foot vein = $10 per ton, mining, milling, etc.
Cost per ton, 30 foot vein, = $2 per ton, mining, milling, etc.
Cost, per oz., 2 foot vein = $10 per oz.
Cost per oz., 30 foot vein = $14 per oz.
Profit per oz., 2 foot vein, $10 per oz.
Profit per oz., 30 foot vein, $6.

The two foot vein, 1 oz. per ton, proposition would call for a small initial installation of plant, say 20 stamps, with corresponding equipment and development. The 30 foot ore body, $3 per ton, would require a comparatively large installation, say 100 to 200 stamps, with proportionate equipment and development, involving a large initial expenditure of capital; the 2 foot vein gives good returns on small initial expenditures. The 30 foot low grade ore body means a large initial expenditure and large scale of operations before any corresponding return can be looked for. The scale of operation of a property is, therefore, an essential factor in its valuation.

Each class of mining venture is a good one, provided it embodies the necessary features for successful operation called for by the limitations of its class.

The small body can be more easily valued; the larger body calls for a careful preliminary sampling, first by ordinary methods of hand sampling, later by operation on a small scale. Successful operations of large low grade ore bodies are more often the result of careful evolution in mining and treatment practice over long periods of time, than the endeavor to earn profits on economies at the start of operations. The ideal conditions for a future large low grade producer are the existence of fair quantities of good grade ore associated with large quantities of low grade ore. The mine can be opened up on the high grades, on a small scale, the initial mistakes made on a small scale, and on a grade of ore that can best afford to pay for such mistakes. Gradually the scale of operations can be extended to that point where the largest quantity of ore of lowest payable grade can be worked. It is always a dangerous method to endeavor to create large operations where there is nothing but low grade ore.

(To be continued)

A SCHOOL FOR RESCUE WORK IN COAL MINES.

"The Canadian Mining Journal" has given prominence to articles on rescue work in coal mines. The vital necessity of properly equipped stations and of facilities for instructing miners in the use of breathing apparatus may be emphasized at any moment by shocking calamities. In all Canada there is only one station where breathing apparatus is kept in readiness for emergencies and where men are trained to meet these emergencies. That station was built and equipped at Glace Bay, Nova Scotia, by the Dominion Coal Com-

"AEROLITH" APPARATUS.

DOCTOR EXAMINING TEAM BEFORE ENTERING THE MINE.

THE WEG APPARATUS, SHOWING CYLINDER.

THE WEG APPARATUS, FRONT VIEW.

CYCLE AMBULANCE.

SIMONS' AMBULANCE CYCLE. It can be fitted as an ambulance in three minutes.

pany. Not only is it the sole establishment in Canada, but, strange to relate, there is no other in all Amreica.

At Glace Bay the Draegar apparatus is in use. We reproduce here another type of apparatus, the "Aerolith."

At Atherton, Lancashire, England, an elaborate model mine has been constructed by the Lancashire & Cheshire Coal Owners' Association. Here novices are trained to meet and overcome the difficulties and obstruction that might be expected after an explosion in an actual mine. The galleries are obstructed and the workings are filled with smoke and sulphuretted hydrogen. In these galleries competing parties of miners set up ventilation walls, remove debris, carry dummies and perform all the duties that they would be called upon to meet in times of real danger. Judges watch the competitors through glass partitions.

The photographs here reproduced are of particular interest. It is not too much to say that our larger mining schools should add a practical course in the use of breathing apparatus to their curricula. No colliery manager's education should be considered complete if it does not include a working knowledge of this subject.

REPORTS OF BRITISH MINES INSPECTORS FOR 1907.

Cardiff District.

The Mines Inspector's report states that 96,265 persons were employed above and below ground at the mines during 1907. Thirteen thousand six hundred and thirty-four of this number were employed overground. The improved price of coal brought about three increases in the miners' wages, which now stand at the maximum of 60 per cent. above the standard of 1879. Twenty-four million six hundred and twenty-five thousand seven hundred and twenty tons of coal, 44,166 tons of fireclay, and 8,195 tons of ironstone were raised. Taking all these into the calculation, 298.6 tons of mineral were raised for each person employed below ground. For each person employed above and below ground, 256.3 tons were raised. The production per person was lower than in any previous year.

One hundred and sixteen thousand four hundred and eighty-four tons of coal were produced by coal cutting machines, whilst in the previous year only 64,135 tons were won by this means. In two cases narrow seams, unworkable by hand, were worked successfully by machines. A total of 17 machines was used, 3 driven by electricity, 14 by compressed air. Ten of these were bar machines, three percussion, three disc, and one chain.

The number of deaths due to accidents amounted to 138. Falls of roof or wall were responsible for 65 deaths; miscellaneous underground accidents, for 50 deaths. In addition to this, 259 persons were injured in the former class of accidents and 210 in the latter. The death rate from accidents per 1,000 persons employed below ground was 1.524, as compared with 1.730 for the year 1906. Tons of mineral raised per life lost amounted to 178,835. In 1906 the figure was 159,879 tons per life lost.

The explosive most commonly used was Saxonite, of which 240,587 pounds were consumed. Out of the total estimated number of shots fired, 964,052, a large proportion, 902,640, were fired by electricity. These figures included only permitted explosives. Gelignite and gunpowder, not on the list, were used to the extent of 120,499 pounds.

In the Cardiff District 89,938 safety lamps were in use. The lead rivet method of locking was used in 52,064 of these lamps and the magnetic on 29,775. The Clanny lamp (shielded, one gauze) constituted a large proportion of the total—84,689.

Swansea District.

As in Cardiff, the relations between employers and employed were uniformly pleasnt throughout the year. In neither district was there any serious stoppage of work due to friction between operators and miners.

At 292 coal mines, 47,179 persons were employed, an increase over 1906 of 5,813. Overground there were 8,459 persons, underground 38,120 persons employed. Twelve million one hundred and fifty-six thousand seven hundred and eighty-eight tons of coal were raised, an average of 1,101,687 tons over 1906. The output of anthracite was 3,498,258 tons, 456,042 tons greater than the previous year's figure.

Forty-nine thousand and seventy-six tons of coal were won by coal cutting machines, as compared with 12,113 tons in 1906. Eleven machines were used, six of which were bar machines. Six were actuated by electricity, five by compressed air.

The deaths from accidents numbered 110, as against 74 in the year preceding. This large increase was due to explosions of firedamp or coal dust, falls of roof and sides, and miscellaneous accidents. The mines were worked under extraordinary pressure. The large number of non-fatal accidents, 458, may be explained by the fact that the new act has the effect of inducing managers to report accidents of a very slight character. Out of the 110 deaths, 42 were attributable to falls of roof or sides. The death rate from accidents underground was 2.66 per 1,000 persons employed.

Saxonite (290,029 pounds) was the most widely used explosive, with Bobbinite (177,084 pounds) second. Gunpowder had 378,892 pounds to its credit, but is not included in the permitted list. Seven hundred and seventy-one thousand and thirty-seven shots out of 1,579,439, were fired by electricity.

The Cambrian (Clanny type) safety lamp is in use more than any other type. The total number of lamps is 26,310, and of these the Cambrian numbers 16,525. 95.5 per cent. of the safety lamps are locked by methods other than the screw method. With the exception of the Protector (6,028 in use) and the Ackroyd and Best (2,445 in use), which are relighted by electricity, the lamps are relighted at lamp station by the exposure of a naked lamp.

NEW MEMBERS CANADIAN MINING INSTITUTE.

The following gentlemen have been elected members or associate members since the annual meeting, March, 1908:

March 3rd, Members—Manley B. Baker, School of Mining, Kingston, Ont.; John Chas. Dufresne, Riondel, B.C.; Geo. Gillespie, 411 Continental Life Bldg., Toronto, Ont.; A. Heathcote, Inspector Mines, Lethbridge, Alta.; Norman L. Leach, Moose Mountain Ltd., Sudbury, Ont. Associates—D. A. Brebner, 1428 Traders Bank Bldg., Toronto, Ont.; J. E. Cook, Temple Bldg., Toronto, Ont.; Jas. McGregor, Latchford, Ont.

March 7th, Members—Thos. Travers, Sudbury, Ont.; J. E. Woodman, D.Sc., Dalhousie University, Halifax, N.S. Associate—Wm. C. Chambers, Harriston, Ont.

April 1st, Members—James Anderson, Ruth Mines, Box 122, Kaslo, B.C.; S. R. Heakes, Supt. Kerr Lake Mining Company, Cobalt, Ont.; J. H. Hubbell, manager Silver Bar Mining Company, Cobalt, Ont.; Lieut.-Col. H. H. Williams, C.E., general manager Broughton Asbestos Fibre Company, East Broughton Station, Que. Associates—Frank L. Cody, managing director Cleveland Cobalt Silver Mines, Limited, Box 179, Cobalt, Ont.; Herman H. Lang, mine manager, Cobalt, Ont.; J. Lorne McDougall, jr., Haileybury, Ont.; A. J. McMillan, general manager Le Roi Mining Company, Limited, Rossland, B.C.; Robert Meredith, Box 722, Montreal, Que.; Clive Pringle, Ottawa, Ont.; Arthur Ross, Box 1122, Montreal, Que.; Geo. E. Sancton, Box 136, Cobalt, Ont. Student—B. Neilly, Bradford, Ont..

May 2nd, Members—H. S. Badger, M.E., Richardson Mines, N.S.; J. W. Bryant, M.E., Box 665, Victoria, B.C.; J. T. Fee, M.E., Cobalt, Ont.; Geo. L. Fraser, mine superintendent, Coleman, Alta.; B. W. Leyson, Cobalt, Ont.; G. F. McNaughton, Cobalt, Ont.; A. H. Sancton, M.E., care Mussens, Limited, Cobalt, Ont.; Bert N. Sharp, M.E., Orient, Wash, U.S.A.; Robt. Turnbull, C.E., 23 Luke street, St. Catharines, Ont.; C. G. Williams, M.E., Cobalt, Ont. Associates—L. O. Armstrong, 221 Milton street, Montreal, Que.; Spencer Benerman, Midway, B. C.; C. L. Campbell, Box 85, Cobalt, Ont.; W. Teese Curran, mine owner, 300 St. James street, Montreal, Que.; E. L. Doucette, Room 53, 112 St. James street, Montreal, Que.; G. A. MacPherson, M.E., Niagara Falls; D. B. Rochester, Cobalt, Ont.; Robt. T. Walker, Cobalt, Ont.

June 28th, Members—Lyndon K. Armstrong, M.E., Spokane, Wash., U.S.A.; C. V. Brennan, B.Sc., Summerside, P. E. I.; G. H. Corbet, M.E., Phoenix, B.C.; Geo. H. Dickson, M.E., Coleman, Alta.; Dr. B. E. Fernow, University of Toronto, Toronto, Ont.; A. G. Larson, superintendent Le Roi Mining Company, Limited, Rossland, B.C.; Fred. S. Peters, Le Roi Mine, Mossland, B.C. Associates—L. C. Butler, president Slipp-Butler Company, 52 Wall street, New York, N.Y., U. S. A.; W. J. Hamilton, Deloro, Ont.; Arthur P. Naismith, Cobalt, Ont.; Samuel Price, St. Thomas, Ont.; Gordon McI. Pyke, Box 893 Montreal, Que.; W. S. Rugh, Le Roi Mining Company, Limited, Rossland, B.C.; R. P. Williams, Rossland, B.C.

Notes on Reports and Maps of Special Economic Interest, Published by the Geological Survey Branch of the Department of Mines.

Economic Geology of Nanaimo and New Westminster Districts, B.C. (issued June, 1908).—Preliminary report on a portion of the main coast of British Columbia and adjacent islands, included in the New Westminster and Nanaimo districts, by O. E. Leroy. This report, while only preliminary, gives a fund of information respecting the economic geology of a portion of British Columbia which, though only partially examined, has already given evidence of being rich in mineral wealth, as well as possessed of immense timber resources, with water power available for their development. Gold, silver, copper, iron, zinc, structural stone in great variety, and clays—some of a very fine, pure character—are all found in abundance, as well as other minerals of lesser importance. An excellent map is incorporated in the report, thus adding practical importance to this publication.

Coal on the Telkwa River, B.C. (issued May, 1908)—A report on the Telkwa river and vicinity, by W. W. Leach, issued by the Geological Survey Branch of the Department of Mines, is of interest from the fact that extensive bodies of coal are known to exist along that river, and its tributary streams, which will be rendered accessible by the construction of the Grand Trunk Pacific Railway. At present, the only means of communication is by pack train; but as soon as the coast section of the Transcontinental Railway is opened, the coal can be shipped direct from the mines to tide water. The country has been only roughly prospected, but many mineral claims have already been staked, and much of the available arable and timber land taken up. A map accompanies the report.

Gold Near Lake Megantic, Que. (Issued June, 1908).—The report of John A. Dresser, on the recently discovery of gold, near Lake Megantic, Quebec, issued by the Geological Survey Branch of the Department of Mines, recalls the fact that alluvial gold was successfully mined for many years on tributaries of the Chaudiere river, which flows out of Lake Megantic. The present discovery is near Victoria river, which empties into the lake. Three separate dikes have been located, in which quartz, carrying small grains of gold, is found. A considerable number of licenses have been taken up along the Victoria river, in the hope that alluvial gold may be found. An assay of a sample taken from one of the dikes shows, in addition to gold ,a small silver value. The report is accompanied by a map.

Tertiary Plants of British Columbia. (Issued 1908).—This is a monograph on the tertiary plants, found in the lignites of British Columbia, and other portions of Western Canada, the material for which was collected by L. M. Lambe, in 1906, the determination of species having been made by Professor Penhallow, D.Sc., F. G. S. A., of McGill University, Montreal. Although much has been accomplished in determining the age of the tertiary deposits, it is still an open question as to the precise horizons within which they fall, and the number of successive stages represented in the tertiary as a whole. The studies contained in this report will help to clear up some of the questions about which there is difference of opinion; and the report brings together, in readily accessible form, a mass of material hitherto scattered and fragmentary.

Report on a Portion of Northwestern Ontario Traversed by the National Transcontinental Railway, Between Lake Nipigon and Sturgeon Lake. (Issued 1908)—The National Transcontinental Railway, now under construction, will open up and render accessible much

territory of which little has hitherto been known. This report describes a district to the north of Lake Superior, which the explorations made by the author—W. H. Collins—show to be possessed of considerable economic value. Gold and iron are the principal minerals—so far as known—and some development work has been done, though not to any great extent. This region, owing to its geological peculiarities, has many lakes and water courses, and water powers exist in every direction. Areas of arable land are to be found, together with an abundance of timber for firewood, and mining purposes. A map, geologically colored, showing the features of the district, accompanies the report.

Moose Mountain District of Southern Alberta. (Issued 1907)—The Moose Mountain district, in Southern Alberta, is rich in coal, and natural gas, and its frequent accompaniment, oil, are also found. This report, of investigations made by D. D. Cairnes, B.Sc., M.E., contains full information respecting the geology of the area, and the economic minerals it contains; with lists of the fossils and the flora there found. A map goes with the report.

Geological and Topographical Map of a Portion of Conrad and Whitehorse Mining District, Yukon Territory. (Issued 1908)—Considerable activity has been going on in the development of the district shown on this map, now rendered easy of access by means of the White Horse & Yukon Railway. The map shows the geological formation, topographical features and mining claims of the district. It has been prepared to accompany a report of D. D. Cairnes, B.Sc., M.E.

Elmsdale Sheet, Hants and Halifax Counties, Nova Scotia. (Issued 1908)—This map shows, in detail, all the features of this portion of the gold-bearing area of Nova Scotia. In addition to the map there is also a section indicating the respective rock formations. The map includes the Renfrew, Mount Uniacke, and Oldham gold districts.

Geological Map Showing Coal Areas in Alberta, Saskatchewan and Manitoba. (Issued 1907)—The coal supply for the western provinces is an economic question of great importance. This map, showing the coal areas, has been prepared to accompany a report by D. B. Dowling, B.A.Sc., and will be of great service in this important matter.

Map of the Auriferous Gravels on Bonanza and Hunker Creeks, Klondike Mining District, Yukon Territory. (Issued 1908)—This map has been prepared to accompany a report by R. G. McConnell, M.A., and conveys much information respecting a district to which much attention has been directed recently, on account of its rich gold mines.

Plan and Sections of the Brookfield Gold District, Queens County, Nova Scotia. (Issued 1908)—This plan, prepared by E. R. Faribault, B.A.Sc., shows one of the gold districts of Nova Scotia, which has yielded considerable quantities of the precious metal.

New Topographical Map of Rossland District, B.C.—Special map of Rossland, B.C., by W. H. Boyd. This map—issued June, 1908—shows the topography of the city and the adjacent mining districts, with contour lines, and details, which cannot fail to be of great service to anyone interested in the development of this important mining centre.

GEOLOGICAL SURVEY PARTIES.

The interim supply bill passed last week has enabled the Geological Survey to get another group of parties into the field.

Mr. W. McInnes has left for South Indian Lake and the Churchill River. The possibility of this country being opened up by the Hudson's Bay Railway in the near future is attracting attention to this region. The upper and lower portions of the Churchill River have already been explored by the Geological Survey. Mr. McInnes will endeavor to fill in the gap now existing. He will try to get in by one route and return by another, to secure additional information as to the geological boundaries, and to examine reported coal and copper occurrences north of Prince Albert.

Mr. W. H. Collins has left for the Montreal River to study the economic geology of the region near its headwaters. The lower portion of the river received a good deal of attention last year from prospectors and promising discoveries were made. The upper portion of the river needs exploring.

Mr. W. A. Johnson has left for Simcoe, Ontario, to continue his topographical and geological work in this sheet covering this portion of the province.

Mr. M. E. Wilson has left for the district north of Lake Temiskaming, in the Province of Quebec. Prospecting for gold is going on in the neighborhood of Lake Opisatica and northeast from Larder Lake on the Quebec side.

Mr. J. A. Fraser is leaving to conduct a geological survey along the line of the national transcontinental from Quebec to the Quebec-New Brunswick interprovincial line.

Mr. G. A. Young has taken a party to New Brunswick to make a detailed survey of a geological sheet covering the iron range near Bathurst.

Mr. R. W. Ells has a party at work in Albert County mapping the oil shales which he will investigate as to their extent and their possibilities in producing petroleum. Dr. Ells is a present in Scotland for the Department of Mines, investigating the oil shale industry in the old country, where for many years it has been successfully conducted.

Mr. E. R. Faribault will be leaving Thursday for Nova Scotia to continue his mapping of the gold-bearing rocks of this province.

Mr. Hugh Fletcher will spend the field season in Cumberland County, Nova Scotia.

Experiments show that while the sedimentary rocks may absorb several per cent. of their volume of water—sandstones 15 per cent., limestones, 5 per cent. and shales 4 per cent.—granites and crystalline rocks seldom absorb more than one-half of one per cent. of their volume, and until within a few years it was thought to be absurd to sink a well in the harder rocks. Frederick G. Clapp, of the United States Geological Survey, has now reported that about 87 per cent. of the wells in granite in southern Maine supply water enough for domestic use. Water percolates very slowly through the rock but more sinks into the vertical joints, and a moderate quantity is stored in the horizontal joints and crevices down to a depth of 200 feet, the amount being so limited that only two out of 72 successful wells yielded more than 50 gallons per minute. The wells are drilled only in the surface rocks, two-thirds being not over 100 feet deep.

THE CANADIAN MINING INSTITUTE SUMMER EXCURSION, 1908.

As previously announced, the Summer Excursion of the Institute will start from Quebec on August 24th.

The itinerary of the tour is as follows, subject to necessary revision en route:

STAGE I.

Monday, Aug. 24th.—Members will assemble at the Chateau Frontenac in the city of Quebec. Visits will be made to the Island of Orleans and other points of interest. The train will leave for Sydney, N.S., late in the evening.

Wednesday, Aug. 26th.—Arrive at Sydney, N.S. (N.B. All arrangements in connection with Nova Scotia visit have been kindly undertaken by the Mining Society of Nova Scotia.)

Thursday, Aug. 27th.—Visit to the Dominion Iron & Steel Company's work.

Friday, Aug. 28th.—Visit to the Dominion Coal Company's collieries, etc. Banquet at Sydney. Late in the evening the train will leavef or Stellarton.

Saturday, Aug. 29th.—The day will be spent in visiting the Acadia Coal Company's colliery at Stellarton. The train will leave the same evening for Sherbrooke, via St. John.

Monday, Aug. 31st.—Upon arrival at Sherbrooke early in the morning, the party will go by the Quebec Central Railway to Thetford, Que., where the day will be spent in visiting the asbestos mines in the neighborhood, and the Canadian Chrome Company's works at Black Lake.

Tuesday, Sept. 1st.—Arrive in Montreal about midday.

Wednesday, Sept. 2nd.—Excursions will be arranged and a reception given by the Local Committee. Leave for Toronto in the evening.

STAGE II.

Ontario Excursion.

Thursday, Sept. 3rd.—Arrive in Toronto in the morning and proceed at once to Niagara Falls, by steamer across Lake Ontario to Lewiston, and thence by Gorge Railway to the Falls, where the day will be spent.

Friday, Sept. 4th.—Leave Niagara. The day will be spent in Toronto, where the party will be the guests of the directors of the Toronto National Exhibition. The train will leave in the evening for North Bay and Cobalt.

Saturday, Sept. 5th.—Arrive at Cobalt early in the morning. The principal mines of the district will be visited, the arrangements being in the hands of the Cobalt Branch of the Institute.

Sunday, Sept. 6th.—Leave Cobalt and arrive Sudbury.

Monday, Sept. 7th.—A visit will be paid to the Moose Mountain iron mine.

Tuesday, Sept. 8th.—Arrive at Copper Cliff. The party will be the guests of the International Nickel Company, whose smelter and Creighton mine will be visited. The company has also kindly undertaken to provide a camp luncheon. Leave Sudbury at midnight.

STAGE III.

Alberta and British Columbia Excursion.

(N.B. The following programme is subject to minor alterations at the discretion of the Local Committees in charge of the entertainment arrangements at the different localities to be visited).

Thursday, Sept. 10th.—Arrive Winnipeg 9.45 a.m. Leave Winnipeg 11.20 a.m.

Friday, Sept. 11th.—Arrive Medicine Hat in the morning, and visit natural gas wells. Leave by special train for Lethbridge, where the afternoon will be spent at the colliery of the Alberta Railway and Irrigation Company.

Saturday, Sept. 12th.—Arrive in Frank early in the morning, where a short stop will be made to enable the party to see the landslide and coal mine. Arrive before noon at Coleman, where the remainder of the day will be spent in inspecting the mines and plant of the International Coal & Coke Company. Special side excursions to Lille, Hillcrest and Bellevue collieries may be arranged by the Local Committee (the Lille mines are equipped with a new power and coal washing plant and the only set of Belgium ovens in the West).

Sunday, Sept. 13th.—Leave Coleman early in the morning, arriving at Hosmer about 9 o'clock. A short stay will be made here to enable the party to inspect the extensive and thoroughly modern colliery established at this point by the C. P. R. After arriving at Fernie early in the afternoon, the train will immediately leave for a visit to the mines at Coal Creek. Leave Fernie at midnight for Moyie.

Monday, Sept. 14th.—The train will arrive at Moyie at 6 a.m., and the morning will be spent in inspecting the St. Eugene (the largest silver-lead mine in Canada) and concentrator. The train will leave at midday to connect with the steamer leaving Kootenay Landing, and arriving at Nelson at 7 p.m.

Tuesday, Sept. 15th.—Leave Nelson at 6.30 a.m. by special train, and arrive at Smelter Junction at 8.30 a.m. Here the party will be permitted to inspect the well-equipped smelter and refinery plant of the Consolidated Mining & Smelting Company of Canada, Limited. The remainder of the day will be spent at Rossland and visits will be made to the Le Roi, Le Roi 2, Centre Star and War Eagle mines.

Wednesday, Sept. 16th.—A special train will leave Trail for Greenwood, arriving at 1 p.m., where arrangements will be made for visiting the very complete copper smelting works of the British Columbia Copper Company, the Mother Lode mine and the smelter at Boundary Falls, owned by the Dominion Copper Company.

Thursday, Sept. 17th.—Special train will leave Greenwood early in the morning for Phoenix, where several hours will be spent in visiting the important mines, including those of the Granby Company, the Brooklyn mine, owned by the Dominion Copper Company, and the Snow Shoe, operated under lease by the Consolidated Mining & Smelting Company of Canada, Limited. In the afternoon the important smelting works of the

Granby Company at Grand Forks will be visited. At midnight a special train will leave for Nelson.

Friday, Sept. 18th.—The day will be spent at Nelson, and arrangements will probably be made for a visit to the Bonnington Falls power plant at Bonnington Falls. At midnight the train will leave to connect with the steamer, which will take the party across the Arrow Lakes to Arrowhead. Arrive at Revelstoke in the evening.

Sunday, Sept. 20th.—Arrive at Victoria in the evening. Three days will be spent in Victoria and excursion will be arranged and a reception given by the Local Committee.

Thursday, Sept. 24th.—Arrive at Vancouver in the morning and visit Stanley Park, leaving by the eastbound train for Banff in the afternoon.

Friday, Sept. 25th.—Arrive at Banff at night.

Saturday, Sept. 26th.—Visit Bankhead Collieries near Banff. Entertainment at luncheon or dinner by the Government of Alberta.

Thursday, Oct. 1st.—Arrive Montreal.

Railway Rates, Eetc.

The railway companies having generously agreed to accord a special rate of half single fare each way via the route travelled, the transportation charges will be approximately as follows:

Nova Scotia—Quebec Excursion (Quebec to Sydney, $9.25; Sydney to Sherbrooke, $7.35; Sherbrooke to Thetford, $1.15; Thetford to Montreal via Sherbrooke, $2.75). Total, $20.50.

Ontario Excursion (Montreal to Toronto, $5; Toronto to Niagara and return, going steamer, returning rail, $2.85; Toronto to Cobalt, $4.95; Cobalt to Sudbury, $2.75; Sudbury to Toronto, $3.80; Sudbury to Montreal, $6.30). Total, Montreal to Sudbury and return, $21.85.

Alberta—British Columbia Excursion (Montreal or Toronto or North Bay to Rossland via the Crow's Nest Pass, Rossland to Greenwood, Greenwood to Nelson, Nelson to Victoria, Victoria to Montreal) $76.85.

(N.B. The approximate rate specified for Stage III. includes the specified rates for Stage II, except the Niagara and Cobalt parts of that Stage.

Sleeping cars will be engaged for the entire trip, and those taking part in the excursion will be required to deposit with the Treasurer an amount covering the charges for the accommodation they desire reserved for each stage. The charge for berths will be as follows:

Nova Scotia-Quebec Excursion, $18.

Ontario Excursion, $15.

Alberta-British Columbia Excursion, (from North Bay), $70.

The Institute will have its own dining car service, and members of the party will be charged at the rate of $3 per day for meals, payable in advance for each stage of the excursion.

In order to secure train accommodation, applications must be received by the Secretary not later than July 15th. After that date the list will be closed and accommodation will not be guaranteed. Applications must be accompanied by deposits subject to forfeiture) as follows:

For the Nova Scotia-Quebec trip a deposit of $25 will be required.

For the Ontario trip a deposit of $25.

For the Alberta-British Columbia trip, $75.

Or for the whole excursion, a deposit of $125.

Berths will be allotted as applications are received.

Railway tickets will be issued by the Secretary before the departure upon each stage of the excursion.

Persons joining the train locally are reminded that they cannot be insured sleeping car accommodation unless they have previously arranged therefor with the Secretary.

H. MORTIMER-LAMB.
Secretary.

PROGRESS WITH THE GRONDAL PROCESS OF CONCENTRATING AND BRIQUETTING IRON ORES.

By P. McN. Bennie, Fitzgerald & Bennie Laboratories, Niagara Falls.

Ottawa Meeting Canadian Mining Institute, March, 1908.

The growth of an art is reflected in the broadening meaning of its definitions. Mining and metallurgy are twin arts so closely related that it is hardly conceivable how they could have had other than simultaneous birth. Mining might be more broadly defined as the art of getting minerals and ores out of the earth, while metallurgy is the art of getting metals out of ores. They make mutual demands upon each other, as, for example, when mining discloses the nickel-cobalt arsenides of the Cobalt district, the ores are laid at the door of metallurgy, with the announcement "There's something new for you, get those things out for us.

Metallurgy makes similar requests of mining, and it is within the province of this paper to recount briefly to what progress the mining of certain kinds of iron ore has been stimulated by the demands of metallurgy.

Last year our laboratories prepared a paper dealing with the magnetic concentration of iron ores by the Grondal process, with some remarks upon the briquetting of such concentrates. This year we are happy to report considerable progress along both lines, as having great interest for Canada, and as indicating that the elements of a very important industry, as yet undeveloped, exist within her borders.

The conditions of supply in the iron ore markets of the old world are in a measure comparable to those which exist on this side, and particularly in the States. Recent years have witnessed the gradual depletion of ores best suited for the Bessemer process, until now there is a universal appeal from the metallurgical world to the mining world for relief from burdens which are becoming heavier year by year upon the

shoulders of pig iron and steel makers. The only visible means of relief seems to be (aside, of course, from the discovery of new ore bodies) some method of improving the quality of iron ore supply, such as an increased iron content, a lowerinlg of slag-forming impurities, with reduction of sulphur and phosphorus to the lowest limits. Magnetic iron ores lend themselves readily to such treatment.

There exist in Sweden and Norway large quantities of magnetic ores ranging from 30 to 60 per cent. iron content, with varying amounts of sulphur and phosphorus. In order to recover a sufficient percentage of iron to make operations profitable, fine grinding is necessary. With fine grinding the iron can be brought up by concentration to between 63 and 68 per cent. Under these conditions the Grondall process of wet concentration gives very satisfactory results. Last year the Engineering and Mining Journal published a list of 19 magnetic concentration plants actively in operation in Sweden, 12 of which now use Grondal apparatus entirely. At the present time there are a number of additional plants under construction, destined to use Grondal apparatus for concentration and briquetting. To show the substantial manner in which treated ores are coming to the relief of the iron ore situation abroad the following is a list of works which are using the Grondal processes for concentrating and briquetting:—

Works.	Tons ore Treated.	Concentrates.	Briquettes.
1. Strassa	150,000	75,000	60,000
2. Bredsjo	40,000	.....	20,000
3. Herrang	60,000	.....	30,000
4. Guldsmedshyttan	90,000	45,000	30,000
5. Uttersbergs	24,000	.....	12,000
6. Flogberget	50,000	.....	24,000
7. Lulea	60,000	.....	50,000
8. Sandvikens	.....	.....	12,000
9. Horndal	.....	.....	12,000
10. Helsingborg	.....	.....	50,000
11. Cwmavon (Wales)	.....	.....	36,000
12. Alquilfe (Spain)	.....	.....	40,000
13. Penn. Steel Co.	200,000	100,000	.....

Where tons of concentrates are not given, the whole output is briquetted. Where only briquettes are given, concentrates or fine or purple ores are used.

There are also under construction the following plants:

Works.	Tons ore Treated.	Concentrates.	Briquettes.
1. Hellefors	20,000	.....	10,000
2. Vigelsbo	20,000	.....	10,000
3. Salangen	300,000	.....	100,000
4. Sydvaranger	1,200,000	.....	600,000
5. Traversella	50,000	.....	25,000
6. Riddarhyttan	20,000	.....	10,000
			775,000

Sydvaranger Development.

The plant under construction at Sydvaranger is an interesting example of the extent to which the exigencies of metallurgy will drive mining into the remote corners of the globe. If anyone should propose to this Institute, as a feasible and profitable plan, the mining of iron ore containing only 38 per cent. metallic iron, in a latitude corresponding to that of our scarcely known Baffin Land, or as far north as the mouth of the Mackenzie River, he would probably be advised to take a complete rest for his health's sake.

Yet such a project is actually under way. A company has been fully financed by powerful German interests, all arrangements made with the Norwegian Government, and comprehensive plans perfected whereby a minimum production of 600,000 tons of concentrates annually will be producer, shipments to begin in 1910. The plant will consist of 40 units each, containing ball mill, crusher, tube mill and separators. At least 100 separators will be required. It has been found that standard Grondal ball mills will handle, on the average, 135 tons of hard magnetite ore per 24 hours.

The company at Salangen, Norway, is composed of certain German iron masters who will themselves absorb the entire annual production of 100,000 tons.

The foregoing has had to do with the commercial development of the Grondal processes. There have been some technical advances, however, of considerable interest, as follows:

(1) The introduction of heavy rock crushers, of the Gates or Blake type, for preliminary crushing, thus throwing less work upon the ball mills.

(2) Where the ore is of suitable character the use of magnetic cobbing machines to get rid of such rock pieces as contain little or no iron. This reduces the amount of ore to be handled in all subsequent operations, per ton of product.

(3) Somewhat finer grinding in the Grondal ball mills. It is generally found that the magnetite particles reduce more quickly than the gangue particles, so that the finer grinding does not necessarily involve reducing all the particles to pulpy condition. The practical effect of such finer grinding is a higher percentage of recovery and a higher iron content in the concentrates. As most of the concentrated material is destined to be briquetted, the fact that the grains are smaller is of no moment.

With regard to briquetting, the following may be noted as improvements:

(1) Better design of briquetting presses, reducing the wear. The life of the die plates has been quadrupled. At Cwmavon, working on pyrites residues, a single set is good for about 500 tons of briquettes.

(2) The original briquetting furnaces and cars were one metre wide. It has been found that this may be increased to 1.5 metres without materially increasing the investment. The result of the change is a 50 per cent. increase in the daily production of the furnace. The furnaces therefore will give a tonnage approaching the nodulizing kiln, with the advantage that the briquettes are more desirable from the metallurgical point of view.

(3) The fuel consumption, which in the one-metre furnaces had reached the low figure of 7 per cent. of the weight of briquettes produced, should be still further reduced in the wider furnaces.

(4) Bilbao spathic ore has been treated very successfully. The ore was first ground in a tube mill to 0.75 mm. mesh. The mill will grind about six tons per hour, using 75 horse-power to drive it. The ground ore was mixed with a little water, pressed and burnt in the usual manner. The original ore ran 47 per cent. iron, which, with the loss of carbon dioxide in the briquetting furnace, brought the iron content of the finished briquette up to 58 per cent.

RESULTS OF GRONDAL METHODS OF CONCENTRATING AND BRIQUETTING

Fuel Economy.

Last year's paper referred to the fuel economy introduced by the use of Grondal briquettes as due to several reasons.

(1) High iron content and consequent small amount of material to be slagged off.

(2) Porosity of briquettes, permitting an enormous surface of contact between reducing gases and iron oxide (this porosity averages over 20 per cent. of the volume of briquettes).

We do not feel that our tests are suffiently complete to warrant positive figures as to fuel economy, as several factors influence the results. We may refer, however, to one test of 1,000 tons of Strassa briquettes, containing 65 per cent. Fe., put through a blast furnace at Cockerills' well-known works, Seraing, Belgium, where a fuel economy of 15 per cent. was claimed. If such results turn out to be actually realisable in practice they would have great significance for Canadian furnace men.

Market Prices.

During the past year the following prices have been paid: For concentrates, containing 68 per cent. Fe., for home consumption in Sweden, about $3.65 per ton, on cars at concentrators. For export, containing 65 per cent. iron and about 10 per cent. water, $4.25 at port of export.

For briquettes, f.o.b. port of export, for briquettes containing 65 per cent. Fe., sales have been made at $5.45 per ton.

Ten thousand tons have been engaged for Germany for this year at about $5.25 at same port. Purple ore briquettes from Helsingborg bring about $6 per ton c.i.f. Stockton. Pyrites resiudes briquettes from the South Wales works command from $5.50 to $6.35 delivered, according to cost of transport. These briquettes contain about 62 per cent. Fe. with sulphur down to 0.044 per cent.

Importance to Canada.

It seems to us that these results contain a lesson to us on this side of the Atlantic well worth a moment's consideration. In the first place, there are in Canada, and particularly in Ontario Province, numerous bodies of magnetite of some extent, which to-day are practically dormant. There is a rapidly growing production of pig iron and steel, with a correspondingly increased demand for ore. Some makers have even had to resort to the use of imported ores. Yet right in Canada there are all the elements of a vast and profitable industry—an industry of basic importance to a country's prosperity—requiring only the awakening touch of intelligent capital to spring into active being.

Without making a plea for any particular apparatus, but assuming that the Grondal methods are employed, two locations present themselves as promising. These are shown as follows:

Central Ontario Valley.

In Fig. 1 is shown an outline of the C. O. Railway, upon which we have marked some of the deposits of magnetitic ores. At some of these deposits there could

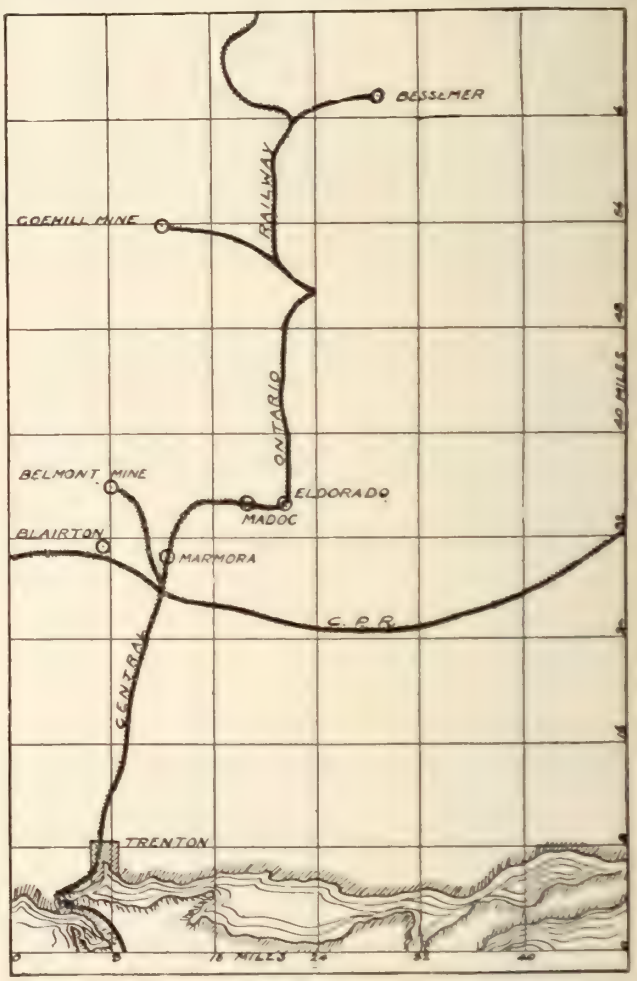

FIG. 1.

doubtless be mined a certain amount of shipping ore, but all of them contain large quantities of ore from 45 per cent. down in iron, which could profitably be treated. The distances from Trenton are approximately as follows:

To Marmora	30 miles.
To Blairton	35 miles.
To Madoc	40 miles.
To Eldorado	40 miles.
To Belmont	35 miles.
To Coe Hill Mines	75 miles.
To Bessemer Mines	85 miles.

Now if a central briquetting plant were to be located at Trenton, to which all materials could be sent, we

would have a plant producing marketable products within an average distance of 50 miles from the mines, which is less than the distance from many Lake Superior mines to nearest lake ports.

Kingston & Pembroke Railway.

Fig. 2 shows a similar scheme, with Kingston as terminus, with the following approximate distances:

To Godfrey	29 miles.
To Verona	25 miles.
To Glendower	35 miles.
To Clarendon	55 miles.
To Robertsville	59 miles.
To Wilbur	67 miles.
To Calabogie	89 miles.

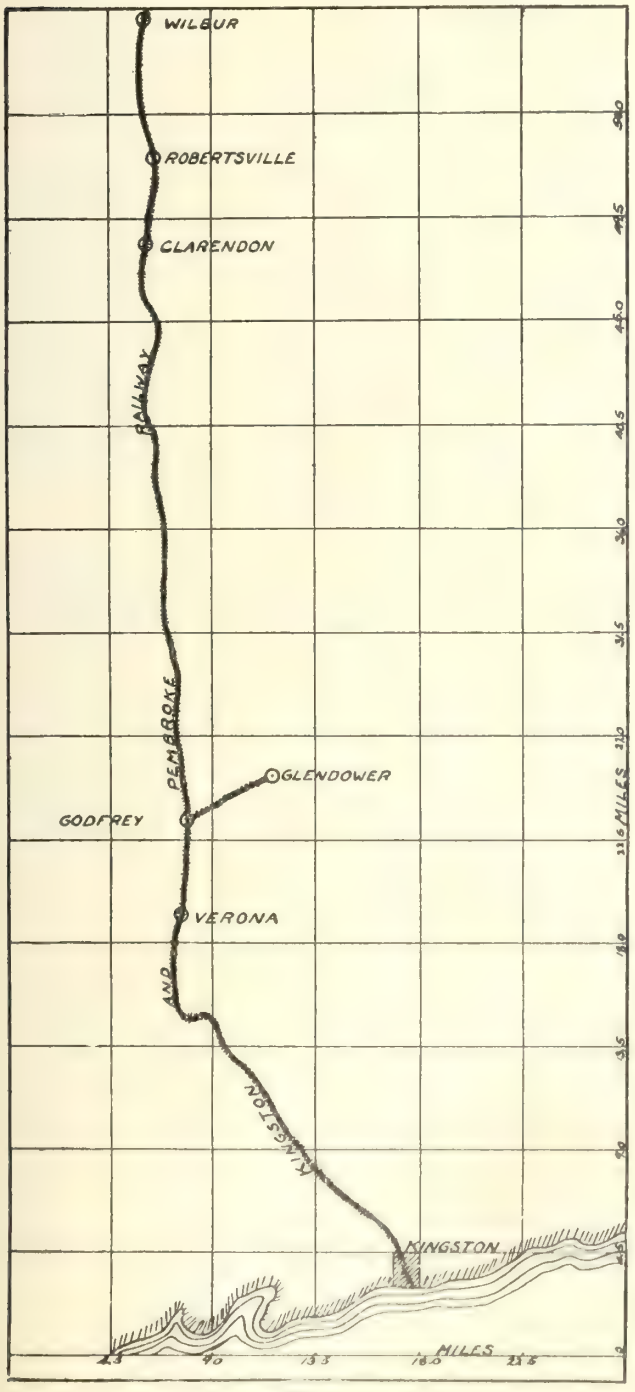

FIG. 2.

From these points an average freight rate of 65 cents a ton could probably be obtained. A central plant at Kingston would be under practically similar conditions with respect to its sources of supply as the Trenton location. It might be found upon close study that it would pay to ship all ores to a central point where both concentrating and briquetting could be done in a single plant under one management.

Cost of Products.

Based upon 40 per cent. ore, as a maxiumum figure of 80 cents per ton loaded at mines, 2 tons would be needed per ton of concentrates	$1.60
Average cost of concentration on a production of 200 tons daily	.40
Cost of concentrates	2.00
Average cost of briquetting on 200 ton basis	.45
	2.45
Freight on 2 tons ore at 65c	1.30
Cost of briquettes	$3.75

Market Values.

Under the above conditions we would have for sale a briquette containing from 63 to 65 per cent. metallic iron, low in sulphur and phosphorus, easily reducible in the blast furnace with economy of fuel; such briquettes would be superior to the average run of old range Bessemer ore, on which the guarantee is now 55 per cent. iron. The present price for such ore is $5 per ton, according to The Iron Trade Review of February 13, 1908. In European and United States markets Grondal briquettes would readily command a minimum price of 10 cents a unit, or $6.30 delivered. This leaves a margin of $2.65 per ton to cover freights and profits. There is no reason to believe that equal selling prices could not be realized in Canada. The Swedish companies using the process have formed the Iron Expert Association, whose products find a plentiful and profitable market in Europe. It is interesting to note that every operating company has been a financial success from the start.

With rich ores commanding a premium and the iron and steel world eager for them, there is no good economic reason why many idle spots in Canada should not teem with this modern industry; why mining should not once more respond to the call of metallurgy.

PERMITTED BRITISH EXPLOSIVES.

The following is a complete list of the names of permitted explosives defined in the schedules to the Explosives in Coal Mines Orders of December 17, 1906, of April 8, 1907, and of May 26, 1908:

Explosives in first schedule:—Abbcite, albionite, ammonal, ammonal B., ammonite, amvis, aphosite, arkite, bellite No. 1, bellite No. 3, bobbinite, britonite, cambrite, carbonite, celtite, cliffite, clydite, colliery steelite, Cornish powder, curtisite, dahmenite A, dragonite, electronite, excellite, extra carbonite, Faversham powder, fracturite, geloxite, good luck, haylite No. 1, kolax, kynite, kynite condensed, minite, monobel powder, negro powder, Nobel carbonite, normanite, oaklite No. 1, oaklite No. 2, odite, permitite, permonite, permonite II, phoenix powder, pit-ite, rexite, ripping ammonal, rippite, roburite No. 3, russelite, saxonite, stow-ite, thunderite, titanite, tutol, victorite, virite, westfalite No. 1, Westfalite No. 2, withnell powder.

Explosives in second schedule.—Bickford's igniter fuse.

A NEW IRON ORE FIELD IN THE PROVINCE OF NEW BRUNSWICK.*

By John E. Hardman, S.B., Ma.E., Montreal, Que.

(*Continued from last issue.*)

The following record of the seven holes drilled is necessarily abbreviated, but for the purposes of this paper will be sufficiently comprehensive.

Borehole No. 1 was located some 200 feet south of the northern end of the deposit found Area No. 1. At the northern end of this area there is a small hill, rising on the southern bank of Austin Brook precipitously to a height of 78 feet, from which height there is a gradual descent to the south of nearly 40 feet, and at the base of this slope and on the hanging, or western, wall of the deposit No. 1 Borehole was put down to a depth of 162 feet. It was in ore continuously from 35 feet to the bottom, giving 127 feet of core which was analyzed for insoluble matter, iron, phosphorus and sulphur, the average length of core represented by each analysis being 10 feet. In this core there was found to be great variation; insoluble matter ranged from 8.04 per cent. to 27.74 per cent.; metallic iron had a minimum of 39.6 per cent. and a maximum of 57.2 per cent. phosphorus varied from .486 to 1.007, and sulphur showed variations from .047 per cent. to .699 per cent. Close inspection of the results when tabulated showed that the ore occurred in bands or strata, ribbon-like, and that these strata were easily separated the one from the other, so that it would be quite posible to hand sort the ore into two piles, one of which would easily exceed 52 per cent. of metallic iron with a minimum of silica, and the other would contain approximately 45 per cent. of metallic iron with the maximum amount of silica. These bands or strata of good ore range from 10 to 25 feet in thickness. Subsequent stripping of the surface clearly showed a banded structure.

No. 2 Borehole was put down approximately in the middle of Area No. I, about 800 feet south of the first borehole. Its depth is 161 feet. It began in iron ore and showed 140 feet of merchantable ore. Like No. 1 hole it shows a banded structure and out of the 140 feet there are 60 feet which average:

Metallic iron 54.11 per cent., insoluble matter 16.7 per cent., phosphorus 0.73 per cent., sulphur 0.098 per cent.

On the bank of the Nipisguit River, and at the extreme southern end of Area No. I, Borehole No. 3 was located but, unfortunately, upon the foot wall instead of on the hanging wall of the deposit; it therefore proved barren, but a sample taken from the surface at this point gave: Metallic iron 51.6 per cent., silica 15.28 per cent., phosphorus .82 per cent., sulphur .05 per cent.

No. 4 Borehole was put down about 450 feet to the westward of the outcrop and about its centre; this made it on the hanging wall of the ore body. The total depth attained by this hole was 527 feet, the first ore was encountered at a depth of 434 feet and for 70 feet, or to a vertical depth of 504 feet, the ore was found continuous and of the same quality as has been shown in the previous analyses.

These four holes proved the existence of an ore body of at least 2,140 feet in length to a depth of 500 feet below the surface, which, in itself, is a very considerable deposit. Of this large amount of ore fully one-half will give 53 per cent. metallic iron and not over 15 per cent. of silica.

Area No. II, so-called, lies about 1,000 feet to the eastward of Area No. I. It presents at least five distinct outcroppings in the shape of knobs or small lenticular masses, the axis of which has a more easterly direction, being north 30 degrees east, as against north 15 degrees east for Area No. I. No boreholes were put down upon this area, which previously had had some stripping done by a representative of the Dominion Iron & Steel Company. From the lines of the magnetometric survey made by Mr. Lindemann it will be fair to assume a length of 1,500 feet for the axis of the ore body in Area II. Surface samples from this Area gave the following anlysis:

Iron	50.23
Silica	15.32
Phosphorus	0.623
Manganese	1.29
Sulphur	0.044
Alumina	0.94
Lime	2.18
Magnesia	0.26

Area No. III. is an oval shaped area lying from 3,000 to 5,000 feet north of the northern bank of the Nipisguit River in Lot 12 of the 17th Range of the Township of Bathurst; the major axis of this area has a direction of north 30 degrees east, and a length so far proved of 2,400 feet. Within this area are half a dozen or more outcrops which, if I may express my belief, will be found to unite when stripping has been accomplished, into one or possibly two large lenses or bodies of merchantable ore. Up to the present time only three drill holes have been put down on this area, which have proved large bodies of a better grade of ore than in Area No. I, and have shown the dip to be to the westward at angles ranging from 54 to 56 degrees.

Borehole No. 5, at a distance of about 700 feet from the southern edge of this area, was sunk vertically upon the hanging wall of the ore body to a depth of over 350 feet. Ore was encountered at a depth of 23 feet, and the core was continuously in ore to 347 feet, showing a vertical depth here of at least 324 feet, or, on dip of 55 degrees, a transverse width of ore in excess of 190 feet. Thirty-three analyses were made of this core in portions representing (with one exception) 10 feet of the core. The same structure was revealed that was shown by analyses of Boreholes 1, 2 and 4, namely, that the ore was composed of bands of excellent commercial grade and 3 bands of a lower grade than is, at the present time, in demand. The first 50 feet of the core, i.e., from 23 feet to 73 feet, gave the following average analysis: Insoluble matter 13.4 per cent., metallic iron 52.68 per cent., phosphorus .99 per cent., sulphur .047 per cent.; this was followed by 50 feet of ore giving over 20 per cent. of insolubles and less than 45 per cent. of iron. Then followed 20 feet with 15 per cent. insolubles, 52.58 per cent. of iron, .752 per cent. of phosphorus, and .05 per cent .of sulphur. This, in turn, was succeeded by 70 feet of ore averaging only 44.3 per cent. of iron and running high in silica and sulphur. After this came 50 feet of good ore, averaging 53 per cent. metallic iron, which in its turn is followed by 40 feet of 46 per cent. ore; the whole concluding with 44 feet of ore, the analysis of which gives 12.25 per cent. of insolubles, and 54 per cent. of metallic iron.

This hole was put down on what, upon further investigation, may prove to be the easternmost bed in this No. II area; at a transverse distance of 250 to 300 feet to the west another series of strongly magnetic lenses appear, but none of them have been drilled. The last

* Incorrectly printed "British Columbia" in last issue.

hole, No. 7, is located about 750 feet north of No. 5; it encountered iron ore at a depth of 30 feet and passed out of the ore at about 107 feet; in this 77 feet there are nearly 60 feet of excellent ore. Beginning at 40 feet in depth up to 83 feet there is a length of core 42 feet 6 inches long, which averages 53.10 per cent. metallic iron, with 17.02 per cent. of insoluble matter. From 91 feet to 107 feet there are 16 feet of ore averaging 54.32 feet metallic iron, with 14.37 per cent. of insolubles.

Consideration of these figures will, I think, clearly indicate that iron ore in very large quantities exists in this hitherto unknown region. The depths to which the boreholes have proved the existence of the iron, coupled with the horizontal extent over which the ores are known to exist, and the widths (which have been measured to average fully 100 feet) demonstrate that the bodies are large.

The analyses of the cores is not altogether satisfactory from a chemical point of view, inasmuch as the method followed (by digestion in acid) does not show the true silica, but only silica plus silicates and other insoluble compounds, which, from the iron master's standpoint, may be a very different matter. In the present case the "insolubles" are really country rock, which has previously been mentioned as igneous. The insolubility of many silicates in strong acids is well known to chemists. The gabbros and diorites of the hanging wall, with the muscovite and chlorite of the foot wall, contain silica percentages ranging from 50 to 80. In the few complete analyses which have been made of the ore (the silica having been determined correctly, either by fusion or by the hydro-fluoric acid method) the actual percentage of silica has ranged from 7 to 12, and there have been found amounts of alumina ranging from .05 to 1.2, lime from 2 per cent. to 3 per per cent., and magnesia from ½ to 1 per cent.

By hand picking or rough lump sorting fully one-half of these large ore bodies can be made to average from 57 to 58 per cent. metallic iron, with 10 per cent. of silica; the phosphorus in such ore will run about 0.88 per cent. and the sulphur 0.055 per cent. With ores of such a character no gentleman conversant with the iron ore markets of the European continent would be disposed to quarrel.

For such a basic ore the demand is now large and steady, and the location of this new field within 20 miles of a sheltered deep water harbor enhances its commercial importance, as ocean shipments from this harbor can be made during at least 9 months of the year.

The property, including some 30 square miles of territory, passed into the control of the Drummond Mines, Limited, in November, 1907, and by this corporation it will be actively exploited this summer; it will also be tested in the furnaces of the Londonderry Iron & Mining Company, although its composition is such as to occasion no uncertainty as to the quality of pig iron obtainable from it.

Although the ore is a non-bessemer, the significance of this new district to Eastern Canada is very great. Iron ores of good quality are scarce in our Dominion, and so far have been at considerable distances from the seaboard; it is, therefore, with the feeling that this new field is well worthy of a preliminary notice, and that it will probably add very largely to the Dominion's resources of furnace ore, that I have ventured to bring this account to your notice.

RULES RELATING TO THE TRANSVAAL STOPE-DRILL COMPETITION, 1908.

Preliminary.

The Transvaal Stope Drill Competition is being organized by the Transvaal Government and the Transvaal Chamber of Mines, which are jointly contributing the prizes, and have nominated a joint committee which has drawn up the conditions under which the competition is to be held, and which will arrange and carry out the competition.

The object of the competition is to obtain a small drill capable of economic use in the narrow stopes on the Witwatersrand, which are at present worked for the most part by hand labor. With this object in view, the committee has endeavored to make the conditions as practical as possible.

To reduce the number of competitors within manageable limits, power is taken to reject or eliminate entries which are obviously outclassed or unsuited to the existing mining conditions.

In the final competition, mining conditions must be taken to mean work in stopes varying in width from 20 inches to 48 inches, and with a dip varying from 20 degrees to 90 degrees. It may be assumed, further, that probably 90 per cent. of the holes drilled will be down holes.

The committee anticipate that all or most of the machines entered will be worked by means of compressed air, the most usual method on the Witwatersrand; but, should any entries offer of machines worked by other kinds of power, the committee will consider such machines.

Competitors who desire to protect their patent rights must make their own arrangements for obtaining provisional protection.

CONDITIONS OF THE TRANSVAAL STOPE DRILL COMPETITION.

A.—General.

1. In these conditions the following expressions are used, with the meanings set against them:

"The committee" means the Technical Committee appointed jointly by the Transvaal Government ond the Transvaal Chamber of Mines to arrange and carry out the competition, or any duly appointed sub-committee or representatives of the committee.

"Competitor" means the person, firm or company entering a machine for the competition. A competitor will be treated as a separate competitor in respect of each type of machine entered by him, the committee deciding what constitutes a different type.

"Machine" means the whole drilling machine, without supports or dust-allayer, provided the supports and dust-allayer are not integral parts of the machine, and does not include the drill.

"Drill" means the jumper.

"Bit" means the cutting end of the drill.

"Elimination trials" means the preliminary trials on surface and underground.

"Competition" means the final trial underground.

2. The decision of the committee in all matters relating to the trials and the competition shall be final. Competitors shall be bound by these conditions. The committee reserves the right to relax, alter or add to the requirements of any of these conditions should it think it desirable in any particular case. The committee reserves the right to repeat the trials or competition or any part thereof in respect of any entry should it think fit.

3. The committee may disqualify any competitor in respect of any or all of his entries, if satisfied on enquiry that he has interfered in the conduct of any of the trials or competitions or has corrupted any miner, or has attempted to do so, or if he refuses to comply with any conditions laid down by the committee. No prize shall be awarded to any entry in respect of which any competitor is so disqualified.

B.—Entries.

4. Entries must be received on or before December 31st, 1908, by the

"Secretary of the Committeee,
Transvaal Chamber of Mines,
Johannesburg,
Transvaal."

Entries must be made on a form which may be obtained at the above address, or from the

"London Secretary,
Transvaal Chamber of Mines,
202 Salisbury House,
Finsbury Circus,
London, E.C."

5. All entries must be accompanied by:

(a) Detailed specifications and drawings.

(b) A list of prices of the machine and accessories, including drills, bars and arms (where such are required) and spare parts, and an illustrated and numbered list of spare parts in triplicate.

(c) A guarantee to the satisfaction of the committee to supply machines and accessories in Johannesburg at the price quoted in the price list, subject to ordinary trade fluctuations in the price of materials.

(d) With respect to the conditions contained in paragraphs (b) and (c) of this clause, if an intending competitor is unable to assign prices to the machine and its accessories, he shall at the time of his entry notify the committee in writing of this fact, and also of his acceptance of the following conditions:

(1) The machine and accessories shall, for the purpose of the competition, be valued by the committee.

(2) The competitor shall enter into an agreement to allow the Transvaal Chamber of Mines or its nominees to manufacture and use the machine and accessories at a royalty of a percentage on actual cost, such percentage to be stated by the competitor at the time of entry.

6. Each competitor shall at the time of entry nominate a representative for all purposes of the trials and competition, who may be either himself or another person. Such representatives must be in Johannesburg throughout the trials and competition, and may be present with his machine at any time. The committee may allow the appointment of an alternate.

7. No entry will be acepted in respect of a machine weighing more than 100 pounds. It is desirable that the machine should be lighter than 100 pounds, as the need of the industry is for a one-man machine.

8. All machines, accessories and parts intended for use in the trials or competition (other than drills) shall be personally delivered free of cost in Johannesburg by the competitor's representative to the committee not later than January 31st, 1909, at such place as the committee shall appoint, and no machines, accessories or parts not so delivered shall be used in the trials or competition, except as desired by the committee.

9. All machines, accessories and parts so delivered shall remain in the possession of the committee, which shall not be responsible for loss or damage in the course of the trials or competition, and which reserve the right to retain any machines or spare parts for the purpose of testing materials.

10. Each machine shall be supplied in a strong box fitted with a padlock, and the acessories and spares shall be supplied in a separate box with padlock.

11. Competitors must supply with each machine a suitable dust-allayer, which may be either a part of the machine, or attached to it, or separate.

12. Each competitor must supply three machines to the committee, and may supply such other machines and spare parts as he may desire, which shall be kept in the custody of the committee and issued for use only with the committee's consent.

13. A competitor may supply his own drills, and may change the supply during the competition on complying with the conditions of Clause 5, but the committee reserves the right to decline to use any drills so supplied if it considers them unsatisfactory.

14. No entries will be accepted which do not fulfil the conditions of Clauses 4 to 13 inclusive.

15. The committee reserves the right to reject the entry of any machine which appears to it, from the drawings and specifications, to be unsuitable in material or design.

16. No entries may be withdrawn except by permission of the committee.

C.—Elimination Trials.

17. To reduce the entries for the first six months' underground competition to a number that can be conveniently handled, elimination trials will be held successively on the surface and underground.

18. The following conditions will apply to the elimination trials, both on surface and underground:

(a) The competitor may, if he so desires, provide his own operator, but the committee reserves the right to put the machine to such tests under its own operators as it may think fit.

(b) All holes drilled shall not be less than 42 nor more than 48 inches in depth (no credit being given for any depth beyond the maximum), and shall be drilled with not more than four steps of gauge. The size of the starting and following bits will be left to the choice of the competitor, but the last bit used shall gauge at least 15-16 inch at the conclusion of drilling.

19. The following conditions will apply to the surface elimination trial only:

(a) Two machines of each entry, or more at the discretion of the committee, will be tested as to their efficiency in drilling down holes in granite blocks.

(b) Competitors may decide the air pressure to be supplied, which shall not be less than 60 pounds nor more than 75 pounds per square inch. In the absence of any requisition from the competitor, the pressure will be 75 pounds per square inch.

(c) Each machine will be tested for one hour actual drilling time, provided that a total of two hours for rigging up, changing drills, drilling, etc., is not exceeded.

(d) The air consumption of each machine will be taken into account in deciding whether such machine has passed the elimination trial.

(e) All entries will be eliminated which cannot drill a minimum of one inch per minute of actual drilling time.

20. The following conditions will apply to the underground elimination trial:

(a) Only machines which have passed the surface elimination trial will be allowed to enter.

(b) One machine of each entry will be subjected to this trial.

(c) The trial will last three periods of eight hours each, such periods to include time spent in changing drills, rigging up, etc.

(d) All trials will, if practicable, be conducted in the same stope at the air pressure prevailing, which shall not be less than 60 pounds nor more than 75 pounds per square inch.

(e) A machine will only be allowed to drill three holes per rig-up, each rig-up to be at least 15 feet from the previous one.

D.—The Competition.

21. At the end of the underground elimination trial, the committee will arrange the entries taking part therein in order of merit with regard to footage drilled and air consumed, and will then decide which may enter for the competition.

22. All machines not eliminated in the previous trials will be entered for a competition under practical working conditions underground, which will begin about April 1st, 1909, and is expected to last six months.

23. Two machines of each entry will be run for 300 shifts each, by day and night, continuously, with the exception of Sundays and legal holidays. The length of shift will be of equal duration on each mine.

24. If any entry of which two machines, in spite of the provisions of Clauses 32 and 35, fail to complete 300 shifts each, the footage drilled shall be charged with the estimated cost of 300 shifts; but time lost through no fault of the machine may be made up with the consent of the committee.

25. The mines and working places in which the competition will be carried out shall be selected by the committee. So far as practicable, each entry will be run for an equal period in each stope in each mine selected.

26. Each pair of machines will in each shift be in the charge of one white miner selected by the committee, with such native assistance as in the opinion of the committee is required.

27. During the competition the machines will do ordinary mining work, in according with instructions given to the miners from time to time by the committee. Not more than two holes on any one rig-up shall be counted, except with the express sanction of the committee. Any number of bars of any length may be used. As far as practicable the conditions under which the diffirent machines work shall be kept uniform.

28. The competing machines will not be required to cut pillars, box holes, etc.; this will be done by the mines.

29. The miner will be forbidden to use any machine or spare parts except those issued to him by a representative of the committee.

30. A reasonable supply of spare parts will be issued to each miner from time to time by the committee as required for each machine operated by him. The miner will sign a receipt for all such issues, and will keep them under lock and key in a box provided by the committee.

31. All worn and replaced parts shall be returned by the miner to the committee not later than the end of the shift in which they were thrown out. A label, signed by the committee's representative, shall be attached to each such part, shewing the period for which it has been in use.

32. If either of the pair of machines at work is so disabled as in the committee's opinion to require to be sent to the surface for repair, a third machine, supplied by the competitor and stored in the working place, shall be issued by the committee to take its place, but such third machine shall be returned as soon as the repair is completed. Machines supplied by the competitor in addition to the three required by Clause 12 shall only be issued with the special sanction of the committee.

33. When any machine is to be moved from a mine or working place in which it has been tested to another, it shall be handed over, together with all spare parts in hand, by the miner to the committee, and checked by the latter. The removal will be entirely under the control of the committee.

34. No machine will be operated at a pressure exceeding 75 pounds or less than 60 pounds per square inch at the end of the pipe line, as shown by recording gauges.

35. The air consumption of each machine will be tested on the surface at least once a month during the competition, at intervals chosen by the committee to afford a good knowledge of the average consumption by the machine underground. While a machine is withdrawn from work for this purpose, its place will be taken by a third machine supplied by the competitor. Should this for any reason be impossible, the time lost may be made up.

E.—Basis of Award for Machines.

36. The first price of £4,000 will be awarded to that entry for which the total cost when divided by the total footage drilled by all machines of that entry during the

competition is least, the committee reserving the right, in case of two or more entries showing approximately equal results, to ignore small difference in points and award the prize to that entry which it considers best suited for the Rand, having regard to weight, general design, ability to drill deep holes, freedom from stoppages and breakdowns, facility of handling, and suitability to norraw stoping.

37. The second prize of £1,000 will be awarded to that entry which is considered by the committee, on the basis laid down in the preceding paragraph, to be second best.

38. The footage drilled shall be measured at the end of each shift. No hole of a depth of less than 42 inches shall be counted, except where authorized in special circumstances by the committee's representative, provided that any hole fitchered at a depth of not less than 30 inches shall be counted. The last bit used shall gauge at least 15-16 inch at the conclusion of drilling.

39. For the purposes of Clause 36 "Cost" shall mean the cost of:

(a) First cost of machines and rig-up gear, less valuation at end of the competition.
(b) Miner's wages.
(c) Native labor.
(d) Air.
(e) Water.
(f) Drill sharpening.
(g) Maintenance.
(h) Stores.

40. As regards the above items the following rules shall apply:

(a) Machines and rig-up gear will be debited to cost at prices fixed as prescribed in paragraph 5, but will be valued by the committee at the end of the competition, and the value so assessed will be taken to credit of the competing machine.
(b) A proportion of miner's wages will be charged, viz., 5s. per machine shift.
(c) Native labor will be charged at a uniform cost per head per shift on each mine throughout the competition.
(d) Air will be charged at a price per cubic foot according to pressure used, as fixed by the committee. These prices will be uniform on all mines.
(e) All water used will be charged at cost.
(f) Drill sharpening and making drills will be charged at cost, which, if competitors supply their own sharpening machines, will include maintenance and depreciation, but not first cost, of sharpening machines.
(g) Maintenance—
  (i.) Spares, including hose and coupling, will be debited as issued; any returned unused being taken to credit.
  (ii) Repairs mean actual shop charges and fitter's time charged at a standard rate fixed by the Committee.
(h) Stores, to include drills, lubricants and waste. Drills will be charged at ruling prices, except when suplied by the competitor, when they will be charged at prices fixed as prescribed in para. 5.

41. Competitors may supply their own drill sharpening machines, but the committee takes no responsibility for their safe return or for any damage sustained. Competitors may, with the consent of the committee, instruct the drill sharpeners, except where otherwise arranged by the committee. All drill sharpening will be done under the control of the committee on the mine where the machine is competing, and by usual drill sharpeners on the mine.

42. Repairs must be done in the shops of the mine where each machine is competing, but competitors may provide their own fitter, who shall not be allowed underground.

F.—Choice of Miners.

43. Miners will be chosen in pairs, to work day and night shifts in partnerships. Mine managers will be asked to nominate pairs of men, who should be machine men chosen on grounds of general intelligence, whether employed on the nominator's mine or not, and to state their qualifications and experience. From the list obtined the number of partnerships required will be selected.

44. Miners will be paid 25s. per shift, with a bonus of one-eighth of any profit made by the committee through the work in the stope in which the miner is employed. Each miner will sign a contract with the committee to work the whole six months of the competition, and to permit the retention of 10 per cent. of his wages till the expiry of his contract. Should he leave before such expiry, except on account of illness or accident or other cause approved by the committee, the amount retained shall be forfeited, and may be paid at the end of the competition to the miner taking his place. A miner temporarily absent through illness, accident or other good cause may be temporarily replaced by a man employed by the committee on day pay.

45. Each partnership will as far as possible work in one stope throughout the trial, and will work in accordance with instructions given by the committee.

46. The committee may dismiss and [or] disqualify for a prize any miner whom it may consider to be incompetent or otherwise unfit for the position.

G.—Basis of Award for Miners.

47. The first prize will be awarded to that partnership whose cost per fathom broken is least, provided that a factor shall be used to equalize the conditions in different stopes, such factor to be arrived at by the committee after obtaining an estimate of the price per fathom in each stope from a sub-committee consisting of the managers and mine foremen of all the mines selected for the competition.

48. The remaining prizes shall be awarded on the same basis.

49. The prizes shall be:—

1st.—£300 to the winning partnership.
2nd.—£200 to the second partnership.
3rd.—£100 to the third partnership.

50. In the event of a prize going to a partnership which has been changed during the competition, the prize money will be divided between the two partners working at the end of the competition according to the time worked by each, but any partner who has left on account of sickness shall receive a share proportionate to the time he has worked.

51. The stopes will be specially surveyed at the beginning and end of the competition, and at such other times as the committee may think necessary, on the

lines laid down in the Interim Report of the Mining Regulations Commision.

52. The costs charged against the miners shall be the same as in the case of machines (see paragraph 39 above), with the addition of the cost of explosives used.

53. A deduction shal be made for fathomage estimated to have been broken by a miner with a machine, the entry of which is withdrawn or disqualified.

BOOK REVIEW.

General Index to Reports of the Geological Survey of Canada—1885-1906. Compiled by F. J. Nicolas. Printed by the Government Printing Bureau, Ottawa, 1908.

The absence of a full and reliable index to the publications of the Geological Survey of Canada has long been a grievance. Searchers for information touching any given topic have had no alternative but to wade in and look through the whole uninventoried stock. Apart from the loss of time thus occasioned, unnecessary strain was put upon the readers' temper. Thus, publications of great intrinsic value have lost much of their interest.

The new index remedies this state of affairs. For the period that it covers it is complete, accurate, and most accessible. Typographically everything is so arranged as to make reference easy and rapid. Cross-references are not multiplied needlessly. Nevertheless wherever necessary ample subject cross-references are given.

The precise accuracy with which all references have been checked is evident on every page. One or two instances will serve to illustrate. On pages 101-102, there are no less than twenty-seven "Black Rivers" classified and differentiated. Under each of the twenty-seven, sub-references are given.

On page 316, under the black-letter title "Fish," there are fifty-six light-type sub-references grouped. These sub-references are again grouped under the sub-titles of provinces. Thus the reader can see at a glance exactly what he wishes to look up and exactly where to find every mention of it.

The reports of field geologists sometimes contain errors in the nomenclature of places, or topographical features. The compiler has avoided -copying these blindly. In all cases of uncertainty or error, the names of localities have been verified and in several instances the authors of reports have been set right.

All of this, of course, was not possible without generous help from Survey officials and others. Mr. Nicolas, indeed, tenders warm thanks to all the officers of the department. Of the assistance of Mr. D. B. Dowling, Mr. Hugh Fletcher, Dr. R. W. Ells, and Mr. W. McInnes he makes grateful mention. He also mentions his indebtedness to Mr. James White, Dominion Geographer, who gave most important assistance in checking over the speling of the names of Canadian localities. Mr. Nicolas also indicates his gratitude to Dr. A. P. Low for constant encouragement and kindly criticism.

The index is a radical departure both in the science of index making (of which it is a brilliant example), and in the publications of the Survey.

The Geological Survey and the compiler are deserving of large credit.

EXCHANGES.

The Iron and Coal Trades Review, June 19th, 1908.—Under title "A Dormant Factor in the Iron Industry" the Review draws attention to the position of France as a future producer of iron ore. Both Germany and Belgium are increasing their demands upon French sources. Sooner or later Great Britain will be forced to purchase ore from France. Meanwhile the Republic conscious of her latent strength, is developing her iron industry rapidly. The present cordial relations existing between Great Britain and France are thus given a commercial significance.

The Colliery Guardian, June 19th, 1908.—Mr. James Ashworth, in a communication to the Guardian, takes up mine watering. The "percentage" of saturation effected by means of any method of watering, varies in different parts of any mine. The deep mine is hotter and drier than the shallow mine. A man working in an atmosphere of 82 to 85 degrees F. can exist only for a limited period. In a warm saturated atmosphere of, say, over 82 degrees F., the perspiration from a man's body cannot pass away and therefore no sense of coolness is possible. Hence watering is inapplicable to deep mines and some other means will have to be found.

The South African Mining Journal, May 30th, 1908—The Journal alludes editorially to the slowness with which dust-allaying devices are being introduced on the Rand. A clause of the Mining Regulations says that no rock drill may be used without means being provided and employed to allay the dust generated in drilling. This instruction is not sufficiently explicit to be effective. Experience has taught that a simple jet of water playing just above the collar of the hole is the method that is most useful and that proves most acceptable to the miners. Although this plan has been adopted in one or two mines with excellent results, it is not yet in general use. It should be made compulsory, at least in drifts and raises. The "extraordinary apathy and even active opposition" of the miners towards steps such as this for ameliorating their hardships, is remarked upon.

PERSONAL AND GENERAL.

Mr. Floyd Harman has assumed the management of the Cochrane mine, Cobalt, Ont. The buildings on this property were destroyed by the recent fire. Rebuilding will be commenced at once.

Mr. J. L. Retallack, who with Mr. Louis Pratt, have spent many months in Ottawa, in the interests of Kootenay lead producers, passed through Toronto on the 26th of June on his way to the west.

Mr. T. R. Drummond, formerly manager of the Dominion Copper Company and, until recently, manager of the Nipissing mine, Cobalt, Ont., has assumed the managership of the Cactus mine at Newhouse, Utah.

Representatives of the Western Branch of the Canadian Mining Institute are to meet the special train at Fernie, B. C. At Victoria a special committee, of which Premier MacBride is chairman, will have charge of the reception.

To entertain the Canadian Mining Institute delegates and their guests the folowing committee of Rossland, B. C., citizens has been appointed: Mayor McDonald, Messrs. R. H. Stewart, P. S. Couldrey and A. G. Larsen. The committee will act in conpunction with the Mayor and city council and the Board of Trade.

Mr. W. H. Boyd has been appointed topographer in charge of the topographical work of the Geological Survey. The excellent topographical work he has done in the west as shown in the Boundary and Rossland special maps, is a guarantee that the general standard of accuracy of the Survey maps will be increased under his supervision. Nothing is of greater utility to the public as a whole than good topographic maps and this recognition of topography by the Survey may be read to mean that topographical work will receive a similar place in the Canadian Survey as has been given it in the United States Geological Survey.

INDUSTRIAL SECTION.

Amatite Roofing.—The objection urged against the use of ordinary prepared roofing is that it requires coating periodically with heavy paint. Amatite roofing is free from this criticism. A top surface of crushed mineral makes painting unnecessary. It is weather proof and so substantial that repairs are not necessary until years of service have been got out of it. A sample will be sent on request by the Paterson Manufacturing Company, Limited, Toronto.

The Jenckes Machine Company, Sherbrooke, Que., Catalogue No. 112, Second Edition, 1908.—In addition to their Sherbrooke works this company has recently erected large branch works at St. Catharines, Ont. The catalogue before us gives descriptions of the Jenckes horizontal tubular boilers, standard smoke stacks, grate bars, rocking grates, high pressure tubular boilers, vertical tubular boilers, steel penstocks, eac. All boilers are tested to ahydrostatic pressure of at least one and one half times their specified working pressure before leaving the works. A boiler inspector's certificate of inspection is furnished at actual cost.

Catalogue 26, June, 1908.—The Jeffrey Manufacturing Company.—The Jeffrey centrifugal fan for mine is the subject of this pamphlet. After a year of systematic testing the Jeffrey Compang has brought out a fan especially designed to meet the demand for large volumetric capacity at low speds and against high water gauges.

The positions and curvatures of the vanes, which discharge the air in a true radial direction, with no dragging effect, are special features of this fan. The bracing is especially strong and does not obstruct the air inlet. Steel is the only material of construction and each fan is assembled and erected, perfectly balanced and marked in every part before being shipped.

Reactions.—A quarterly bulletin distributed by the Goldschmidt Thermit Company, is filled with interesting reading. The Thermit Process is applicable especially to rail welding. The operation of welding can be performed without interruption to traffic. A gang of four men can make 20 or more joints per day. The Thermit weld has been used for a wide range of work, from steel ladles in copper smelters to the rudder frames of large steamships.

The process is based upon the reduction of metallic compounds by aluminium. The reaction is accompanied by a considerable evolution of heat and propagates itself from one point until the entire mixture is affected. As a means of starting the reaction barium proxide is found most satisfactory.

The Goldschmidt Thermit Company has opened a branch at 103 Richmond street West, in this city. Contracts for welding heavy sections, such as crank shafts, locomotive frames, etc., will be undertaken. At the shops, repairs on small castings, not exceeding 1,000 pounds, will be performed.

The Behrend Dry Concentrator For All Ores.—The ore must be fairly dry, crushed, pulverized and screened to certain sizes, which are determined by the physical conditions. Thus it will be understood that successful concentration depends upon economic capacity, and perfection of the preliminary work to insure high grade effect in the operation of concentrating machines.

The new concentrating machines operate on the principle of air exhaust. The current enters into the lower end between the table and top dressing plate, a point where the concentrates are discharged, the air force, which can be perfectly regulated, carrying with it the lighter gangue matter down into the base of the machine onto baffle boards, and when sufficient weight has accumulated upon a flexible outlet valve, said valve opens and discharges the tailings. The table being rapidly vibrated, the heavier concentrates travel in the opposite direction and are discharged at its lowest end where the air current enters, as above specified. The finer material, dust from the raw ores undergoing dressing, is carried on through with the exhaust air into and through a duct to dust chamber if desired, or into the open air outside of the building.

The machine works entirely on the principle of specific gravity of materials under treatment. By simply lowering the dressing plate, which contracts the space through which the air is drawn, the force is so concentrated that only mineral of the heaviest specific gravity contained in the material can be discharged. The lighter minerals will be carried over as tailings, and these can be run to a second machine for the separation of the next heaviest specific gravity. In this manner the several minerals in concentrates can be readily sparated.

By referring to the outline drawing, Fig. 3, it will be seen the air enters at A, and is carried over the entire surface of the table S, the arrows indicating direction. The tailings discharge at B. The table is under rapid vibration by the eccentric C. The ore is fed into the table through the false bottom and pocket D. The

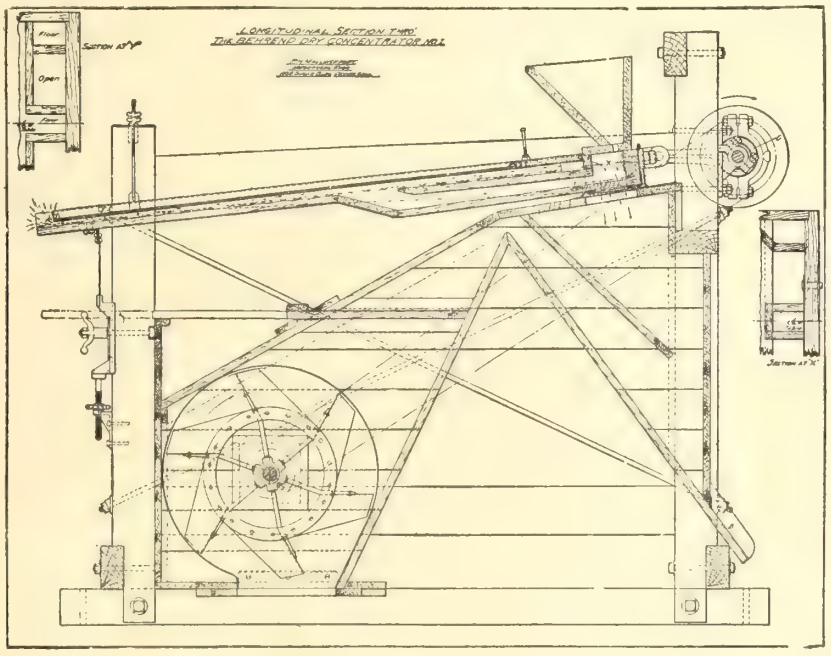
dressing plate entirely covers the table and, combined, constitutes the air flue. Said plate is moveable in a perpendicular line, which can be raised or lowered, creating a variable air current, according to the gravities of material under treatment, to insure discharge of any degree of concentration desired. The volume of air and ore feed is also under complete control.

The operation of the machine, as before outlined, is very positive and simple. When adjusted to discharge the concentrates, it requires absolutely no attention beyond occasional inspection, to insure continuous and highly efficient work; consequently, it requires no expert ability, merely eyesight. A person of ordinary intelligence could operate 50 machines as efficiently as a man of skill at high wages.

A very important consideration in connection with employment of the Behrend system of concentration is, that a mill of this description can be installed contiguous to the mine, instead of hauling the ore to a mill at some remote place where water is available,

2. Silver-lead ore, baryta gangue from West Cliffe, Col., recovery 90 per cent. lead.

3. Silver-lead ore from Cashier Mining & Milling Company, Boulder County, Co., recovery 90.2 per cent.



4. Bismuth ore from New Mexico, 95 per cent. extraction.

5. Tungsten ore, Boulder County, recovery, 90 per cent.

6. Tellurium ore, Cripple Creek, Col., value $5.25 per ton, recovery 75 per cent.; value of concentrates, $65 to $172.

7. Canadian corundum; extraction 75 per cent.

8. Ore, silver sulphides, gangue of quartz and baryta, which had never been concentrated to any commercial degree by any system; recovery 75 per cent. From various sizes operated upon the following products and values were obtained from "mill dirt" having an average value of 24 ounces silver per ton: 201.68 ounces per ton, 242.60 ounces per ton, and 440.56 ounces per ton.

frequently imperative in any country, at a cost which would make the difference between profit and loss.

The capacity of the concentrating machines is eight to fifteen tons, according to sizes operated upon, in 24 hours, the average being twelve tons. The weight of a machine is 500 pounds, and it can be transported to almost inaccessible places in mining districts. The floor space required is 3½ by 6 feet. Power required is ½-horse power.

The advantage to be derived by employment of the Behrend concentrators in only one phase of the system, is excess extraction, or higher degree of concentration over the wet system. Comparative tests showed gains of 10 to 30 pr cent. at less cost.

The following record of work done by the Behrend concentrators represents only a few of the incidental tests made:

1. Ore containing lead, 9 per cent.; zinc, 12 per cent., the other constituents being iron and silica. Results: 70 per cent. lead concentrates, the iron carrying less than 1 per cent. lead, about 3 per cent. zinc, and the zinc product was brought up to 40 per cent.

The above tests were made on "mill dirt" from tunnels, drifts, stopes and dumps of the Blue Bird mine, Grand Island district, Boulder County, Co.

A testing plant under the Behrend system is maintained at 48½ Inspector street, Montreal, Que., where the machine can be operated on all ores.

STIBNITE IN FRANCE.

The auriferous stibnite of Martigne-Ferchand, France, occurs in a greenstone dyke which courses through black and yellowish-brown, fine grained, porous quartzites. The dyke is 33 feet wide. It can be traced for nearly a mile. The stibnite contains 0.0009 per cent. gold, and the ore also includes arsenical pyrites carrying 0.0008 per cent. gold, iron pyrites, limonite, and occasionally a little native gold. The gangue consists chiefly of quartz and calcite, with some brown spar associated. Vugs and druses, occur frequently. The lodes are probably the infilling of contraction-fissures in the greenstone. The industrial importance of the Martigne stibnites is much lessened by the arsenic present.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.

The referendum vote of the members of the P. W. A. has come and gone, and the result was a small majority in favor of the American organization. The total eligible membership was 10,000, so it is said, but of this only about half cared sufficiently about the matter to go to the poll. The character of the vote is interesting, varying according to the locality. Pictou county, as one would expect of the descendants of so distinguished an ancestry, went solid for the native organization. Cumberland county, who are without doubt the Athenians of Nova Scotia, desired a change. In the Glace Bay district it was noticeable that at those collieries that have traditions and are come of age the vote was for the Canadian body. At the more youthful collieries it was the reverse. It can hardly be said that a majority of 500 out of a vote of 10,000 is at all conclusive, especially when one considers the energy that was displayed by the U. M. W. A. advocates and the apathetic indifference manifested by the rank and file of the P. W. A. So for the nonce. like the man in the song, "we dunno where we are."

One well known text book on mining, in its introduction, lays down the axiom that a colliery "the conditions are never ideal." which same is most true. During the first half of June it looked as if the mines of the Dominion Coal Company were going to beat all records, and reach a mark that would stand for a long time, but they didn't. The output was 343,000 tons, which is about 4,00 tons less than that of October, 1907. The reason that the output was not larger was an accident to the haulage engine of Reserve colliery, which laid the mine idle for several days. The Hub mine produced 13,700 tons, and from now on the outputs from this mine will be normal. The Emery mine, No. 10, produced 15,500, the largest output from that mine as yet.

It is surprising what remarkable statements are offered for public consumption, and are meekly swallowed by those who don't know better. A Montreal paper recently quoted some Halifax shareholder of Dominion Steel stock to the effect that "there was not a coal owner in Nova Scotia who would not sell slack at $1.24, if he were sure of a market the year round." We venture to assert that there is not a coal owner in Nova Scotia who could sell slack at $1.24 per ton all the year around and keep clear of the Bankruptcy Court. Such statements are the most arrant nonsense, indeed they are a little worse than nonsense. There was a time in the coal trade when slack was a drug on the market, but it is not so to-day. Modern methods of firing boilers, the use of bye-product ovens, and other contributory causes have put slack on about the same footing as runmine, indeed there are many firms who buy runmine, and afterwards crush it to slack, as they prefer it that way. Improved methods of mining make less slack, and it is a far cry to the old days when thousands of tons of valuable coal were left in the mines in the form of riddled slack at the time when miners were paid for round coal only. But even if slack were a difficult thing to sell it could not be sold at $1.24. If anyone doubts this, let him try to buy it in Nova Scotia at that price, and his doubts would quickly vanish.

No. 12 Colliery is emerging out of chaos. The bankhead foundations have been excavated, concrete culverts laid down. and the concreting of the air shaft is about completed. Several of the permanent colliery buildings are already erected, and altogether a good deal of construction work has been done during the recent fine weather, considering the difficulty of transporting material before the completion of the railway branch.

Mr. Dennis, of the Geological Survey at Ottawa, has recently visited the mines of this neighborhood, and taken samples of the coal coming over the screens ot different collieries. This has been done for the purposes of the admirable work now being carried on by the staff of the McGill University, under the direction of Dr. Bonsall Porter, namely the determination of the commercial worth of all Canadian coals, and a classification of their analyses, washing tests, boiler tests, etc., similar in character to the monumental work of the Coal Testing Bureau at the St. Louis Exposition some time ago. The various and numerous samples of Canadian coals that are awaiting treatment in the buildings of McGill is an eloquent commentary on the wealth of the Dominion in commercial coals. When the work the McGill people are now engaged on is completed it will afford a very valuabel mass of data of a kind that has never previously been collected in Canada, and its publication will be awaited with considerable interest.

ONTARIO.

Toronto.

A representative of the "Canadian Mining Journal" inspected the exhibit of gold ore from the Harris-Maxwell property, Larder Lake, now on view at the office of the Toronto Star.

The ore is the typical silicified dolomite, rusty in spots and seamed with quartz stringers. Disseminated throughout the specimens are iron pyrites, a little chalcopyrite and galena and possibly a little zinc blende. These sulphides occur in small spicules and amount to not more than one per cent. of the total weight of the ore. Visible gold is sprinkled freely along the quartz stringers when they come in contact with the country rock. The specimens on exhibition are rich.

This is an encouraging symptom. While it is by no means to be taken as conclusive evidence of Larder Lake's value as a mining field, the finding of this striking specimen ore certainly justifies continued development.

QUEBEC.

Montreal.

A promising discovery of asbestos has recently been made on lot 16, range 4, township of Thetford, at a distance of about four and a half miles from Thetford Station. Asbestos was known to occur on this lot for several years, but little attention was paid to this until about one week ago when a rich shoot in the southwestern corner of the property was located. The quality appears to be the same as found in the Thetford and Black Lake mines. Veins measuring one inch and over, yielding an excellent crude No. 1 were found, while veins of smaller width in immediate vicinity cover an area of about 125feet long and 50 feet wide.

On lot 17, the adjoining lot, veins of half inch have been found in the southeasterly part over an area of about 50 by 40 feet.

It is likely that the Robertson serpentine range, which seems to have a large extent is a continuation of the famous Thetford serpentine, which has contributed so largely to the world's output of asbestos for the last ten years. No work to speak of has yet been done on these new discoveries, but judging from the remarks of an asbestos expert who has made lately a thorough examination of these deposits, the districts will in all probability become a producer of fibre of some importance.

Mr. F. M. Whitney, head of the American Asbestos Company at Black Lake, has sold out his interests to the British-Canadian Asbestos Company for a large cash consideration, retaining, however,, $400,000 of shares in a new company to be formed with a capital of $2,000,000. The American Asbestos Company in 1900 took over the property known the Murphy lot, close to the railway works of the Quebec Central, at Black Lake. A mill of a capacity of 500 tons of rock per day was built, which since 1904 has produced as an average continuously about one car load of asbestos fibre and clay. Last year the company bought the old asbestos properties of the Glasgow and the Manhattan, adjoining, and since that time in addition to the mill fibre has produced from 40 to 50 tons of crude per month. The new company will continue operations for the present as heretofore, but innovations and improvements of a large extent are contemplated for 1909.

BRITISH COLUMBIA.

Victoria.

The threatened abandoning of the Kaslo & Sandon Railroad by the Great Northern has aroused strong protests from these places. The Government of British Columbia has acted promptly in support of this protest by sending an official telegram to the Great Northern.

The Kaslo & Slocan Railroad was built under a provincial franchise. A bonus of 400,000 acres of land was given along with other valuable concessions. The land is now worth a great deal. The line runs from Kaslo on Kootenay Lake to Sandon, a distance of about 20 miles. A short branch connects Sandon with Cody, further up the valley.

Recently the train service has been cut to three trains per week. The Great Northern now intimates its intention of cutting off Sandon and Cody altogether by building a Y at McGuigan Siding and running the trains from Kaslo to McGuigan and back. They contend that as two costly bridges have been destroyed by landslides, the Sandon traffic does not justify their replacement.

Should this plan be carried out Sandon would be cut off from communication with the rest of South Kootenay. Slocan is only 21 miles from Nelson. But if the change is made it will be necessary to go round by way of Nakusp, a distance of 125 miles.

In the memorial sent to the Premier by the residents of Kaslo it is pointed out that, while the new arrangement would afford accommodation to the Rambler-Cariboo mine, which ships from McGuigan, and to the Lucky Jim at Bear Lake and to the Whitewater mines, it would cut off direct communication between Kaslo and Sandon for freight, passengers and mails and would deprive all the mines at Sandon of an alternative and competing outlet for ores. Moreover, the Last Chance, American Boy, Sunset, Reco, Goodenough, and other mines tributary to the Cody branch would be forced to haul their ores to Sandon by team, a distance of one to three miles.

Whilst the petitioners admit that the road has not been a paying one since its acquisition by the Great Northern, they draw attention to the large concessions obtained by that railway. In accepting these concessions and in exercising its right of appropriating private lands the Great Northern has incurred corresponding obligations to the Government and to the public. The railway owns a large system of lines in British Columbia and is constantly adding to these. It is not fair that the corporation should be allowed to abandon portions of its undertaking that prove temporarily unprofitable, while retaining the profitable propositions.

The Sandon camp is but now recovering from a period of extreme depression. It is believed that the depression was brought about by accidental causes, such as litigation and management, and not through any exhaustion of ore bodies. The camp, encouraged by the renewed bounty upon lead and by the prospects of a market for zinc ores, is entering upon a new and promising phase. The Great Northern should not be allowed to discourage a renewal of active mining operations.

It is also pointed out that by the proposed change a gap of ten miles will separate Kaslo and Sandon and the industrial, commercial, and domestic relations of eleven years' growth will be ruptured.

It is practically certain that the Government will intervene.

YUKON.

Dawson.

All the Yukon is watching keenly the new method of mining auriferous gravels of the northern creek bottoms, which is being undertaken on the famous Bonanza Creek, a few miles from Dawson. The new method is to hydraulic the bottoms, and carry away the gravel with aid of an electrically driven lift or conveyor, resembling in principle the operation of a chain of buckets on a dredge. It is the first practical test ever made in the north with a conveyor or lift driven with electricity. Similar conveyors on a rougher scale have been driven in this country with steam, but the expense of generating the steam made them impracticable for operating anything but very rich gravels. The Yukon Gold Company, better known as the Guggenheims, are the originators of the electrical process here.

The low cost of power is the mainstay in this undertaking. The power will be used to lift water from a sump hole at the bottom of the conveyor, about fifty feet, to the tailing race, as well as to drive the buckets. The power is generated on Twelve Mile River, 35 miles distant, and brought over the hills by direct trunk wire. Pelton wheels driver by the river water generate the power.

The Guggenheims are planning to have three of the elevators erected this season. The process seems so certain to be a success that the company has not hesitated to make this heavy initial expense, which not only includes the purchase and installation of 100 tons of material to each conveyor, but also the carrying of the water many miles from the head of Bonanza, piping along the creek bottoms, digging of long open cuts, and other expensive incidental work.

Should this creek bottom process prove successful, and to most it seems there is no doubt of it doing so, the venture will be the cause of revolutionizing the methods of working creek bottoms. The conveyors are expected to be superior to dredges from the fact that the conveyors will clean out all overburden and gravel and leave the bottom, so that as much of the bedrock as desirable can be taken up, and the remaining surface cleaned with water, brooms or otherwise, insuring the recovery of all gold in the creek bottom. The dredges, on the other hand, have to work under water, and the working of the bedrock cannot be done nearly so satisfactorily.

One of the new conveyors has all the capacity of a dredge. In general appearance it looks like a huge steel skeleton tower, thirty feet square at the bottom and 12 feet square at the top, with long steel rods running up from each corner, forming the legs or general supports. It is to be mounted on rollers, and can be moved along the creek with aid of winches. As the gravel is washed into the sump by the hydraulic heads, it is caught in a string of buckets, which rotate over a ladder reaching from the bottom of the main frame work to the top, and standing at an angle of 75 degrees most of the way up, and graduating near the top to 45 degrees, before turning the tumbler at the top. Seventy-six buckets each with a capacity of three cubic feet comprise the bucket line. From the base to the top of the elevator is 59 feet. The buckets turn just below the

uppermost part of the frame, and, as they do so, throw the gravel into elevated sluices, of about the same height as the top of the bucket line.

One man standing on a platform at the top of the conveyor has before him several winches, with which he controls every motion of the big machine. Switches at one side will control the electrical motors driving the conveyor, and the pumps, so that the one man literally will be able to start and stop the whole works at will.

The procession of gravel, silt and other material which will be lifted by the buckets will require water equalling a small creek in volume to wash it through the sluices, and properly wash it, dissolve the plastic matter and relieve the gold. The sluices are three feet wide, and three feet deep, have a grade of six inches to 12 feet, and run back 40 to 60 feet from the conveyor, branching so as to distribute the tailings. These sluices, compared with the narrow primative sluice boxes of the sourdough miner, or even the Klondike kings of old make the old specimens appear like pigmies beside a Hercules. The sluices of the conveyor are more like a large flume, and that they virtually are, with the riffles set in the bottom to catch the gold. Through these giant sluices will be poured 14 sluiceheads of water of 50 inches each, a total of 700 inches. This water will be lifted from the sump, and in lifting it a double service will be rendered, namely, clearing the sump of the flow from the hydraulic heads with which the gravels of the creek are being torn down; and in properly washing the gravels.

Two twelve inch pumps, especially designed for this work, will lift the water. Each pump will be driven with a seventy-five horse-power electrical motor, set on a platform in the middle of the conveyor frame. Beside these motors is one of the 50 horse-power motors which will drive the bucket line.

Two giants, with a total capacity of 500 inches, will tear down the gravel, and shoot it along the bedrock into the sump. In addition, there will be some water let in from the Bonanza Creek to ground sluice the muck and otherwise assist the giants. The extra water from other sources than the nozzles is found very essential in hydraulic work. It is needed to give greater volume to the stream in washing down the silt and gravel, as well as in groundsluicing. The total water pouring into the sump from water and nozzles and creek will have to be controlled so as not to exceed 700 inches, the capacity of the two pumps which keep clear the sump. Most of the time water going into the sump will run perhaps somewhat under the capacity of the pumps, thus not overworking the pumps. While it is planned to use but two giants at a time, there will be others supplied, into which the water may be diverted at any time. Each giant will require five sluiceheads of water. The head will be furnished by a drop of 350 from a penstock on the right limit, fed by the water conveyed from above the upper Bonanza dam by the Norwood ditch.

Before starting to work the ground, the claim will be cut in the middle with a bedrock opening, running lengthwise of the creek, and leading into the sump. In this opening will be set a string of steel sluices. Into these central sluices will be washed all the gravel and other moveable material above bedrock, and most of the gold will be caught in these sluices. What is not caught there will go through with the gravel, and be washed in the big sluices after leaving the conveyor buckets. Thus the gravel by the new method virtually is worked over twice in quick succession.

It is expected that it will be possible to work 400 feet up stream from the conveyor with the giants before it will be necessary to move up the conveyor. The gravel at No. 3 above is about 15 feet from surface to bedrock, and has very little overburden. With the width of creek existing there, which is 400 to 500 feet, it probably will be all one conveyor will be able to do to work out one claim of 500 feet in length in a season. This much done, and the bedrock thoroughly cleaned will be quite an accomplishment. As soon as the creek claims are worked, and the bedrock cleaned, the creek tailing then can be dumped promiscuously into the valley, and the tailings will rise mountains high.

Twenty-five to thirty men will be required to attend to the ground and all the works about each conveyor night and day. All being satisfactory, as many conveyors can be supplied along the creek as is consistent with the water supply and the life of the conveyors in proportion to what will be a reasonable number of machines to do the work profitably.

The first of the conveyors has been completed, and the work undertaken this month, but it is not yet to be said to have turned over enough to have been given a thorough test. The plant will run day and night when well started. O. B. Perry, manager of the company, is the originator, it is understood, of the new conveyor. Should it prove a success, many of these conveyors no doubt will be installed in the Yukon country by other companies.

Bob Henderson, discoverer of the first gold in the Klondike valley, and his partner, Bill Forbes, left on the steamer Victorian, the first boat of the year up the Yukon from Dawson, for the Pelly River, where they will prospect this season. They will pole up the Pelly 300 miles, to a locality where they spent much of last summer.

They found gold on many river bars and on a number of creeks on the Pelly last year, and return there confident that a good camp will be opened in that country in time. Bob has many samples of gold from the district, and always has been enthusiastic over that field.

McLeod and others have been prospecting up the Pelly this winter, and it may be that they will have good news. No direct news of the results of the prospecting in the Pelly has been received this spring. Van Vibber and Van Gorder, who live in the last cabin on the last creek, 500 miles up the Pelly, have been expecting to find gold in time. They are so far up the Pelly as to be but a short distance from Findlay River.

Canada may look forward to the Yukon as a future field for the sale of large quantities of first class mining equipment. The country has evolved rapidly from the days when wood fires, and then boilers and hoists were the only apparatus needed in working the ground for the placer deposits. Quartz mining is beginning, but placer is yet the chief industry. Scores of extensive large method mining plants have been installed in the Klondike since the region began to evolve from the old conditions of individual operation. The investment in dredges and hydraulic equipment have reached many millions, and this line of enterprise seems scarcely more than begun.

In connection with the dredges extensive outlay has been necessary for steam and water power plants, for generating of electricity, with which the dredges are driven. For each hydraulic plant long ditch lines often are necessary, necessitating in many instances extensive outlay for pipe material for syphons, to say nothing of the need of hydraulic giants and the other parts aside from lumber for flumes, penstocks and such.

The new style of electrically driven elevators or lifts for handling tailings from ground being worked by hydraulic on the creek bottoms also calls for extensive mechanical equipment. The frame work of the lifts are entirely of steel, and carry a steel bucket line, similar to a dredge, and are equipped with two large centrifugal pumps to each lift, for handling of water from the sump to the tailing boxes. The hydraulic giants used for washing the gravel down to the lifts are akin to the hydraulic plants used in the operations on hills.

The electrical equipment for conveying power is one of the biggest items of expense. Lines from a quarter of a mile to sixty miles long are installed already conveying power, and heavy wire, and transforming stations add to the quantity of equipment materially. In connection with each such line also is the generating equipment in form of dynamos driven by turbines or steam plants.

Some of the dredges are supplied with power from steam boilers aboard the craft, but the larger concerns have their steam or water power plants ashore, and electrical lines with which to convey the electricity to the dredges. The several big companies branching out are planning the installation of extensive power plants of most modern character. The power will be generated largely from the vast natural water courses, and conducted over hills and valleys with copper wires. In some instances there are plans to generate power at the coal mines, so as to avoid hauling the coal, and to transmit the power by wire direct from the mines to the place of consumption.

The many new hill groups organized for working on hydraulic plans will be demanding much more new equipment before long. Flumes, ditch line and pipe line material and giants and such will come largely into demand as a consequence.

The prospecting of the dredge ground also makes a demand for more modern equipment, in the way of large drilling machines. The keystone drill is the favorite for this purpose in the Yukon, and no less than ten are in use within ten miles of Dakson. These drills cost laid down at Dawson $3,000 and $4,000 each.

The dredges in use in the Klondike camp cost on the average $140,000 to $150,000 each, completed on the spot ready for starting. Of this cost approximately one-third is represented in the the purchase price of the machinery at the factories. The remainder is for lumber, transportation and labor.

The fleet of dredges now in operation within 75 miles of Dawson including the following:

Dredge No. 1 at mouth of Bonanza, working on claim 104 below discovery, owned by Guggenheims.

Dredge No. 2, on 104 below on Bonanza, owned by Guggenheims.

Dredge on 90 below discovery, Bonanza, owned by Guggenheims.

Dredge No. 91, Bonanza, owned by Guggenheims.

Dredge at mouth of Hunker, owned by Guggenheims.

Dredge on Anderson Concession, Hunker, owned by Guggenheims.

Dredge on 37, Hunker, owned by Guggenheims.

Dredge at mouth of Bear Creek, owned by Canadian Klondike Mining Company.

Dredge at mouth of the Klondike River, owned by the Bonanza Basin Gold Dredging & Mining Company.

Dredge on Bonanza, owned by the Lewis River Dredging & Mining Company.

Dredge on Indian River, owned by Indian River Gold Mining Company.

Dredge on lower Forty Mile River, owned by the Consolidated Gold Mining Company of Alaska.

Dredge at Boundary on Forty Mile River, owned by Consolidated Gold Mining Company of Alaska.

Dredge on South Fork of Forty Mile, owned by Mosier & Company.

Dredge on lower Walker's Fork of the Forty Mile River, owned by the Gold Scoopers' Company.

Dredge on upper Walker's Fork of the Forty Mile River, owned by Russell King and associates.

In addition to this is a dredge being assembled at this writing at Whitehorse for operation this season on the Stewart River by the Yukon Basin Gold Mining Company. The same company is planning the installation of several more dredges in subsequent seasons.

Several other large dredges also are being planned by other companies.

The hydraulic plants being operated near Dawson this season include:

Two giants on Acklen Group, right limit of the Klondike, opposite the mouth of Bonanza, 700 inches, owned by Guggenheims.

Two giants on Paradise Hill, left limit of Hunker, using 300 inches, owned by Guggenheims.

Two giants on Solomon Hill, left limit of Bonanza, using 400 inches, owned by Guggenheims.

Two giants on American Gulch, left limit of Bonanza, using 500 inches, owned by Guggenheims.

Two giants on Bunker Hill, right limit of Bonanza, using 500 inches, owned by Guggenheims.

Two giants on No. 3, above Bonanza, hydraulicking creek bottom into electrical lift No. 1, owned by Guggenheims.

Four giants on Adams Hill, owend by Bonanza Creek Hydraulic Company.

Seven giants on French Hill, left limit of Bonanza, owned by Detroit-Yukon Mining Company.

Plant on Whiskey Hill, right limit of Hunker, operated by Blanchfield & McCrimmon.

Plant on Whiskey Hill, operated by Joe Burke.

Giant on Paradise Hill, owned by Bert R. Elliott.

Giant on Delhi Hill, operated by Delhi, Rice & Peterson.

Plant on Temperance Hill, Hunker, operated by French Syndicate.

Giant on Temperance Hill, Hunker, operated by August Larson.

Plant on Temperance Hill, Hunker, operated by August Larson.

Plant on hill opposite Bee Gulch, operated by Detroit-Yukon Company.

Plant on Nugget Hill, opposite 55 below, operated by Gould & Murphy.

Four monitors, with 800 inches, working on Treasure Hill, Hunker, owned by Dolan & Tackstrom.

Two giants on left limit of 3 and 4 Last Chance, owned by Collins & Eilbeck.

Two giants, opposite 2 and 3 below on Hunker, operated by Jim Younkins.

Two giants opposite 9 below, Last Chance, operated by Jack Day.

Two giants opposite 6 above the mouth, left limit of Last Chance, owned by Jim Wilson.

Plant on Last Chance, operated by Rogers & Holland.

Plant on Goring Creek, opposite upper Hunker, owned by Miles, Grey and Cunningham.

In addition to the foregoing are several plants operating on Lovett Gulch and other points along Bonanza and Hunker by individuals whose namee are not known.

In the Forty Mile country hydraulic work also is being undertaken by quite a number.

On Ballarat Creek, above Dawson, the Consolidated Company of Alaska has several giants.

Thistle Creek also has some hydraulic plants in course of installation.

On Barker Creek, a tributary of the Stewart, Graham and partner are installing a plant. The ditch is completed.

Hydraulic work also has been carried on quite extensively on the French Syndicate's ground on the Sixty Mile.

The N. A. T. & T. has an extensive hydraulic plant, long ditch and hydraulic lift on Miller Creek. The company also is clearing the ground there for dredge purposes.

Many large hills in the Klondike camp are being prepared for operation by hydraulic methods.

In the Circle district, at Rampart, Hot Springs, which are on the lower Yukon, hydraulic plants have been undertaken on extensive scale. These three districts are among the most important in the Yukon basin.

On the extreme upper Yukon waters are the tributaries of the Big Salmon, where plants are working on several creeks, including Livingstone, Cottoneva and other streams.

In the Atlin district, the waters of which are tributary to the Yukon, hydraulic work, with many large flumes and ditches, has been under way for years. Dredges and steam shovels also are used there.

The Klondike's new hydraulic plants will include the several to be fed by the mammoth ditch now being completed at a cost of five to ten thousand dollars, sixty miles over the hills from Twelve Mile River to the high levels of Bonanza and Hunker. Much of this water will be used to feed electrical conveyor plants.

The first of the electrical conveyors has been installed on Bonanza at a heavy cost, probably about $50,000, and containing 100 tons of machinery and steel frame materila. Two more of the plants are to be installed on Bonanza this season. Part of the machinery for the two plants is on the ground. The Guggenheims own the big ditch and the conveyors. The ditch will carry 5,000 inches of water.

The hydraulic and dredging mining has been under way in Klondike not more than three years, that is on anything more than a limited scale, and while millions have bee nexpended in ventures of this kind already, the working here by this method is barely begun.

The tailing heaps from the hydraulic plants are becoming decidedly noticeable on Klondike creeks. The immense quantity of gravel handled by the giants as in comparison with the old methods employed by the early miners affords a sharp contrast in size of tailing piles. Near discovery on Bonanza the tailings from off the left limit extend the full width of the creek, and are being banked high above the creek level with brsuh buttresses. The sheer rise on the outer edge makes a picturesque spectacle. The green brush lends a sharp contrast in color to the white mass of gravel showing on the surface. Over the whole spreads the stream of water from the sluices, carrying the gravel and sediment to all parts of the huge pile. There is no telling how high these brush walls will have to be built. Already they are 10 to 30 feet high, and the tailing pile, extending lengthwise of the creek feet, makes an imposing pile.

At the mouth of Eldorado is another huge tailing pile, extending the width of the creek, leaving a narrow place at one side for the water of the stream to pass.

As soon as the creek bed of Bonanza is worked out with dredges or electrical ifts, the building of bulwarks to retain tailings no longer will be required, and the tailings from the hills will be thrown over the brow of the hills into the creek bottoms with little trouble in keeping clear any space below unless it be merely sufficient opening for the water to pass down stream without backing up high enough to damage the road.

GENERAL MINING NEWS.

ONTARIO.

Toronto.—Government bounties during April were paid on 43,118 barrels of petroleum produced in Southwestern Ontario.

The Court of Appeal for Ontario has delivered judgment dismissing with costs all three appeals from the judgment of Chief Justice Meredith in the case of Crawfod vs. the Lawson Mine, Limited, and McLeod vs. Crawford. These two actions were originally brought in connection with the long disputed title to the famous Lawson mine. Mr. Crawford demanded certain rights in connection with the Lawson mine, and Mr. Duncan McLeod and others interested in the property proceeded against Mr. Crawford and Samuel R. Clark, to enforce an agreement of settlement made April 6th, 1907.

The judgments of the Chief Justice were not satisfactory to the litigant, and three appeals were made to the Court of Appeal. One was by Thomas Crawford in connection with the dismissal of his action against the Lawson Mines, Limited, and John McMartin. Another was brought by Thomas Crawford and Samuel R. Clark, against the judgment in favor of the plaintiffs in the other action, and the third by the same defendants against the judgment in favor of Messrs. Millar & Bedells upon their counter-claim. All the appeals were heard together, the argument occupying more than three days. Their Lordships reserved judgment in order to afford an opportunity for perusal of the voluminous exhibits in connection with the case.

The judgment says: "It is needless to repeat the reasoning of the learned Chief Justice that the agreement was not capable of bing enforced, because it purports to be made with a company not in existence. But it may be pointed out that the agreement of the 3rd of April did not alter the relation of Thos. Crawford as a trustee of the land for himself, Murdoch McLeod, Donald Crawford and John McLeod, or their representatives."

The judgment repeats several other findings, and concludes:

"For these, as well as for the reasons given by the learned Chief Justice, the appeals in the action of McLeod vs. Crawford fail and must be dismissed. And it follows that the appellant, Thomas Crawford, had no ground for the action instituted by him against John McMartin, and that it was rightly dismissed at the trial.

"All three appeals are dismissed with costs."

Ottawa.—Hon. Mr. Fielding has given notice of the following resolution in the Commons: "That it is expedient to provide that the bounty of one-half cent per imperial gallon on crude petroleum from Canadian wells, authorized by the act of 1904, shall apply to crude petroleum produced from shales or other substances mined in Canada."

Cobalt, July 8.—The "blind pig" will soon be a thing of the past. The authorities have awakened. For two days the local police court has been kept busy. Fines ranging from $50 to $150 and a total of $1,750 have been imposed. Forty "blind pigs" have been struck and seventeen convictions resulted.

Cobalt Lake.—Bulletin of progress, Cobalt Lake Mining Company:

Mining.—The drift in the north shaft is out underneath the lake a distance of 45 feet. This machine during the month drilled 33 feet and cut out the level station, and in addition the lower portion of the shaft has been timbered and planked and a substantial head frame erected over its mouth.

No. 4, 1st Level.—The north crossent is now in 377 feet from No. 3 or 480 feet from the drift on No. 4, making the driving for this machine during the month 59 feet and in addition this machine sunk a winze on the No. 3 vein to a depth of 10 feet and is also responsible for a proportion of the ore broken down during the month. The ore broken during the month amounted after cobbing to 46 tons, most of which was broken by the

"baby" machine. A crosscut to the south is now in a distance of 522 feet, making the driving for this machine for the month 62 feet.

Second Level.—The west drift is now out underneath the lake a distance of 259 feet, and in addition this machine drove 12 feet to the east from the north crosscut and upraised 4 feet, making 36 feet feet of footage for this machine for the month.

No. 6—The north drift is now out 87 feet and the east drift 34 feet, making 76 feet of driving for this machine for the month.

Our total footage during the month was 306 feet.

(Signed) E. L. Fraleck.

P.S.—The ore bagged this month consists of 1½ tons of first grade silver ore, 30½ tons of cobalt ore and 6 tons of cobalt ore, a total of 46 tons. We have on hand at the present time 27½ tons of silver ore, 12 tons of second grade silver ore, 85 tons of cobalt ore and 32 tons of niccolite, making in all 156½ tons.

We purpose shipping out a car of first grade silver ore on Monday, and also expect to ship one car load of cobalt ore on Tuesday, to the same parties os we shipped the last one and on the same conditions

(Signed) D. B. Rochester.

NOVA SCOTIA.

Halifax.—June 24 was the day appointed for the 10,000 voters of the P. W. A. to decide whether that organization would remain an inedpendent entity or be merged in the U. M. W. A. A large vote was expected; but only slightly more than one-half of the possible votes were polled. Incomplete returns gave the U. M. W. A. a majority of 400.

Sydney.—Rumors are current that the Harmsworths are negotiating for the purchase of the Buchell coal areas at New Campbellton. The areas comprise five or six square miles near the entrance to Big Bras d'Or Lake. Several miles of submarine areas are also included. The Harmsworths are taking up the matter with a view to securing cheap fuel for their Newfoundland pulp enterprise.

Stellarton.—The Intercolonial Coal Company has discovered by boring a new seam of coal within the town limits of Stellarton.

Westville.—A fatal accident occurred at the Drummond Colliery on June 17th. A fall of rock instantly killed Duncan MacMaster.

Port Hood.—As a result of test boring near the Seaside Wharf the Port Hood-Richmond Railway Coal Company has struck the overlying 8 foot seam. This was cut at a shallow depth. The seam was exposed many years ago but was covered by drift. Old inhabitants remember when the outcrop was visible. Sand washed in from the bar covered it, and until now it has been but a tradition.

Truro.—Near Moose River gold mines, Halifax County, scheelite has been found in drift. Areas have been taken up and parties are prospecting for the mother lode.

BRITISH COLUMBIA.

Fernie.—James Ferguson was instantly killed at Michel, No. 5 mine, of the C. N. Pass Coal Company, on Friday, July 3rd. Loaded cars broke loose and the unfortunate man was killed instantly.

Greenwood.—Mr. P. J. Roosa has been appointed manager of the Dominion Copper Company's mines and smelter in succession to Mr. W. C. Thomas, who has accepted an appointment in Utah. Mr. Roosa was for five years Mr. Thomas' chief of staff. He has the confidence of the community. Mr. John Cawile is to be general foreman of the smelter. There are no changes in the list of mine officials. The 750 ton furnace was blown in on the 28th of June. The two small furnaces will not be blown in until an up-to-date electric feed process is installed.

Vancouver.—The discovery of a belt of copper ore at Tasso Harbor, Queen Charlotte Islands, has been reported here.

Victoria.—A well authenticated report has it that negotiations are in progress for the purchase of the Wellington Collieries, controlled by Lieut.-Governor Dunsmuir. John Arbuthnot, ex-Mayor of Winnipeg, and Luke Wishart, of New York, are concerned in the transaction. The consideration is said to be upwards of $5,000,000.

Atlin.—In spite of the desertion of this camp by the Guggenheims there is every prospect of a good clean-up for the season. On Pine Creek the North Columbia Hydraulic will operate, and on McKee Creek the McKee Creek Consolidated will be active.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The North of England Branch of the National Association of Colliery Managers have submitted to the general body a resolution favoring the establishment of a rescue station in some central position for Durham and Northumberland mines. They embodied with it an expression of opinion that the practical possibilities of the use of breathing apparatus were being exaggerated to a degree which might prove dangerous.

Many extensions and new enterprises in connection with the development of the Northumberland coal fields are reported. Shipments from this field have greatly increased and the output for the first six months of the year will probably be a new record.

FRANCE.

The Societe de l'Industrie Minerale, the most important mining and metallurgical association in France, celebrated its jubilee anniversary held by a congress at St. Etienne from June 14th to June 20th, which was attended by 436 engineers. Visits were paid to leading collieries and steam works. Mr. Bennett H. Brough presented a congratulatory address from the British Iron and Steel Institute.

Nine miners were suffocated in the Montmartre No. 2 pit of the La Loire mines near St. Etienne, on June 22nd. They were engaged in constructing barriers against a fire which had broken out in the mine and the ventilation was cut off.

RUSSIA.

The extensive Briansk iron and steel works in South Russia, principally owned by French capitalists, have closed down indefinitely.

By a fire, which broke out on the 3rd inst., at the Rikovsky mine, Yusovo, followed by an explosion of gas, over 200 miners

were killed. The rescue work, which resulted in saving many of those in the mine, was conducted under great difficulties, six of the rescuers being among the victims.

SPITZBERGEN.

The coal mines worked by the Trondhjem American Spitzbergen Coal Company have been extended and deepened and regular workings will be begun in August. The Anglo-Bergen Company mined 4,000 tons during the winter and will supply the Norwegian State railways and sell to steamship companies in Norway.

AUSTRALASIA.

Mr. Menzies, the discoverer of the Menzies gold field in Western Australia, prospecting in the northern territory of the Commonwealth, has discovered tin deposits of value on the Fitzmaurice fall of the table-lands country. Specimens show over 70 per cent. of tin.

A new copper field is being opened up at Mount Balfour, on the northwest coast of Tasmania, where work has been undertaken at several points.

Mr. H. Y. S. Brown, Government Geologist of South Australia, states that 21,000,000 tons of iron ore averaging 66 per cent. iron and manganiferous iron are in sight at Tron Knob, 40 miles from Port Augusta.

The mines at Broken Hill, New South Wales, are rigidly economizing in view of the decrease in metal values. Staffs are being reduced and development restricted.

UNITED STATES.

At the San Antonio mine in the Red Mountain district, Colorado, a body of copper ore 30 feet long by 25 feet wide has been found, giving every indication of being persistent in depth.

A large number of zinc mines in the Joplin, Missouri, district, have been closed down owing to the expense of keeping them free from water and the present low price of zinc. Some of the mines are installing better pumping machinery.

Copper production in the Butte disteict of Montana will show a considerable falling off on account of floods. About 7,000 men are employed in the Amalgamated mines, the output of which is about 8,500 tons of ore per day. The Great Falls smelter of the Boston & Montana Company, which was greatly damaged by flooding, is likely to be out of commission for some time.

The School of Mines building of the University of Nevada at Reno, the gift of Clarence H. Mackay and Mrs. John Mackay, which cost $750,000, was dedicated last month. Mr. Mackay also promises an endowment fund for salaries.

CHINA.

A mining company has been formed with $2,000,000 capital to work the iron, coal and galena mines near Okran, the principal stockholders being Chinese in Hong Kong and Singapore. The project includes the erection of smelters and a narrow gauge railway to tide water.

PHILIPPINE ISLANDS.

Gold dredging appears likely to become a profitable undertaking, as there are large tracts of alluvial gold-bearing land, which preliminary tests indicate to be worth working. About 80 ounces gold valued at £300 were recently sent down from the Paracale district.

MEXICO.

An explosion in a mine belonging to the Mexican Coal & Coke Company killed twenty Mexican and Japanese miners.

The enactment of the proposed new mining law excluding foreigners from acquiring mining properties has apparently been indefiinitely postponed.

STATISTICS AND RETURNS.

The output of the Dominion Coal Company's collieries for June is estimated at 347,000 tons. This would bring the total output for the half year up to 1,924,619 tons, or an increase over the corresponding period a year ago of 170,899 tons, which, on the whole, is a very satisfactory showing.

Mr. James Ross in London stated the year's output will be close to 4,000,000 tons and at the present rate that figure will be reached.

The output by months is as follows:

	1908. Tons.	1907. Tons.
January	314,108	252,248
February	285,649	225,988
March	346,529	212,831
April	298,745	316,384
May	332,588	327,269
June	347,000	319,000
Total	1,924,619	1,653,720

The output of the Crow's Nest Pass collieries for the week ending July 3 was 17,957 tons, a daily average (five days) of 3,591 tons. All collieries were idle on Dominion Day. Week ending July 5, 1907, 17,748 tons; daily average, 3,549 tons; week ending July, 1906, 11,692 tons; daily average, 2,923 tons.

The corrected returns, by collieries, of the Dominion Coal Company's outputs are as follows:

OUTPUTS—JUNE, 1908.

No. 1 colliery	52,316
No. 2 colliery	66,851
No. 3 colliery	36,052
No. 4 colliery	38,836
No. 5 colliery	39,758
No. 6 colliery	23,178
No. 7 colliery	13,665
No. 8 colliery	21,384
No. 9 colliery	35,339
No. 10 colliery	15,527
	342,906

Shipments from the collieries of the Cumberland Railway & Coal Company, Springhill, N.S., for the month of June were 29,041 tons.

COBALT ORE SHIPMENTS.

Shipments of ore from the Cobalt camp for the week ending June 27th totalled 820,270 pounds, or 405 tons, divided among eleven mines.

	Week ending June 27.	Since Jan. 1.
Buffalo	42,680	696,390
Coniagas	63,210	631,890
City of Cobalt	116,400	568,510
McKinley	58,120	1,615,280
Nipissing	62,400	2,045,400
O'Brien	63,320	3,008,740
Right of Way	60,480	363,770
Temiskaming	120,000	445,000
Tretheway	133,500	1,264,226
Watts	60,160	306,180

Following are the weekly shipments from Cobalt camp, and those from January 1 to date:

	Week ending July 4.	Since Jan. 1.
Buffalo	.....	696,390
Coniagas	.....	631,890
Cobalt Lake	.....	246,455
Crown Reserve	.....	84,000
Cobalt Central	.....	156,380
City of Cobalt	46,870	615,380
Drummond	.....	188,600
Foster	.....	238,400
Kerr Lake	.....	462,300
King Edward	.....	127,240
La Rose	62,240	2,508,562
McKinley	120,000	1,735,280
Nipissing	111,340	2,156,740
Nova Scotia	.....	271,545
Little Nipissing	.....	40,110
Nancy Helen	.....	140,420
O'Brien	212,730	3,221,470
Right of Way	.....	363,770
Provincial	.....	143,210
Silver Queen	.....	634,510
Silver Cliff	.....	52,000
Silver Leaf	.....	196,620
Townsite	54,600	130,700
Temiskaming	100,000	545,000
Temiskaming & H. B.	60,000	724,000
Trethewey	108,180	1,372,406
Watts	.....	306,180

The total shipmetns for the week were 866,960 pounds, or 433 tons. Total shipments from January 1st are 18,220,348 pounds, or 9110 tons.

Of the shipments for the week ending July 4th 147,850 pounds went from the Obrien mine to the Deloro smelter. The same mine shipped 64,880 pounds to Denver.

La Rose shipped 62,240 pounds to the Anglo-French Nickel Company, Swansea. The Copper Cliff smelter received 45,600 pounds from the Cobalt Townsite and 16,870 pounds from the City of Cobalt mine.

BRITISH COLUMBIA ORE SHIPMENTS.

The shipments from the mines and the receipts at the smelters of the districts of Southeastern British Columbia for the week ending June 27 and year to date were as follows:

Ore Shipments:

	Week.	Year.
Boundary	32,423	570,051
Rossland	5,396	137,200
East of Columbia River	1,330	47,713

The total ore shipments for the past week were 39,149 tons, and for the year to date 754,964 tons.

Smelter Receipts:

	Week.	Year.
Grand Forks	22,011	522,823
Greenwood	11,089	48,005
Trail	5,241	133,502
Northport (Le Roi)	1,450	41,358
Marysville	.....	5,730

For the week ending July 4th:—

Boundary:	Week.	Year.
Granby	20,522	543,345
Mother Lode	5,940	40,170
Oro Deloro	1,190	13,666
Rawhide	1,500	1,506
Sunset	450	450
Brooklyn	104	104
Mt. Rose	45	45
Other mines	...	522
Total	29,751	599,802
Rossland:		
Centre Star	1,815	85,469
Le Roi	1,540	39,978
Le Roi No 2	645	15,099
Other mines	...	552
Total	4,000	141,098
Slocan-Kootenay:		
St. Eugene	600	10,375
Whitewater	143	512
Whitewater, milled	280	7,420
Poorman, milled	185	5,850
Queen, milled	185	4,800
North Star	34	1,428
Richmond	72	957
Arlington, Erie	70	810
Rambler Cariboo	20	688
Sunset	42	166
Westmount	44	91
No. 1	14	14
M. & H.	10	10
Other mines	...	16,389
Total	1,764	49,477

The total shipments for the past week were 35,518 tons and for the year to date 790,377 tons.

SMELTER RECEIPTS.

	Week.	Year.
Granby	20,522	543,345
B. C. Copper Co...	7,751	55,756
Dominion Copper Co...	2,099	2,099
Trail	5,603	139,105
Le Roi, Northport Wash .. .	1,690	43,070

The total smelter receipts for the past week were 37,665 tons and for the year to date 789,105 tons.

According to the estimates of Kaffir houses in London, the June output of Transvaal gold falls below May, which was the high record, but was above every other month except March. The output was 570,000 ounces fine. In May it was 581,992 fine ounces. The value of the June output, calculated on the basis of the above estimate, compares as follows:—June, 1908, $12,112,000; May, 1908, $12,360,000; April, 1908, $11,924,000; March, 1908, $12,210,000; February, 1908, $11,510,000; January, 1908, $11,900,000; June, 1907, $10,780,000; June, 1906, $10,109,000; June, 1905, $8,757,000; June, 1904, $6,546,000; June, 1903, $5,062,000; June, 1902, $3,032,000.

The imports of zinc ores into the United States for the first five months of 1908 amounted to 10,900 tons, of which 5,796 tons were classified as dutiable.

COMPANY NOTES.

A half-yearly dividend of three and one-half per cent (3½ per cent.) has been declared on the preferred stock of Dominion Coal Company, Limited, payable on August 1st, 1908, to shareholders of record at the closing of the books on July 31st, 1908.

Transfer books of the preferred stock will be closed from July 21st, at 3 p.m., until August 1st, at 10 a.m.

Sir George Drummond and Mr. E. S. Clouston have resigned from the Cumberland Railway & Coal Company, and two new directors were elected at the annual meeting.

The new directors are Mr. Percy Cowans, of McDougall & Cowans, members of the Montreal Stock Exchange, and Mr. J. D. Hayden, of Cobourg.

Sir Geoorge Drummond was president of the company, and is succeeded by his son, Mr. Huntley Drummond.

Mr. Edgar Macdougall was elected vice-president, and Messrs. David Maurice, W. J. Maurice, J. R. Cowans, G. L. Cains, W. G. Crossen, P. P. Cowans and J. D. Hayden, directors.

Mr. J. R. Cowans was elected general manager, and E. Laflamme secretary-treasurer.

This company has its properties at Springhill, N.S., and in Cape Breton, the coal areas in the latter place being leased recently on a royalty basis to the Dominion Steel Company.

A report submitted by an outside expert shows the properties to be in splendid shape.

Bell's Asbestos Company, Limited, have declared an interim dividend of 1s per share free of income tax for the half year ending 30th June, being at the rate of ten per cent. per annum, payable by warrant on and after the 1st August to the shareholders on the register on the 23rd proximo.

The share transfer books will be closed from the 23rd July to the 30th July, both days inclusive.

MARKETS REPORTS.

Coke.

July 7th—Connellsville coke, f.o.b. ovens—
Furnace coke, prompt, $1.55 to $1.60.
Furnace coke, prompt, $1.90 to $2.

Amatite ROOFING

Amatite has one distinction which makes it stand out above all others. *It has a real mineral surface.*

It is hardly necessary to state the advantages of such a mineral surface, the freedom from painting or coating, the perfect protection against all kinds of weather, the great durability.

This mineral surface is embodied in a layer of Pitch, *the greatest known waterproofing material.* Beneath this in turn are two layers of the best grade of wool felt—cemented together by more Pitch, making the whole a roofing that is *absolutely waterproof.*

No other ready roofing can compare with this mineral-surfaced, waterproof, weatherproof, durable roof. *Don't buy your roofing until you have seen Amatite.*

MINERALS

and how they occur

A Book for Secondary Schools and Prospectors

BY

WILLETT G. MILLAR

Provincial Geologist of Ontario; formerly Professor of Geology in the School of Mining, Queen's University, Kingston, Canada

252 pages; price $1.00; post paid. Boards

Dr. Miller's text-book, new in its third edition, has undoubtedly met the requirements of prospectors and students. It is simple in diction, and logical in plan. It comprises exactly the information needed by the beginner and, because of its clearness and simplicity, it is distinctly of value to all classes of mining men.

"Minerals and How they Occur" can be obtained from the Canadian Mining Journal.

Position wanted by Mining Engineer as Superintendent or Mining Captain.

I have had over twenty-five years experience in Mining work, being for twelve years engaged at my last position in Gold Mining, and for ten years Master of Iron Mines in North Michigan: For several years Superintendent of other mining enterprises: Highest reference: Will accept any reasonable offer: Age 46: Married: Strictly temperate.

For two years I have made investigation of mining properties in the Cobalt District, North Ont., Canada.

To Mining Investors and Capitalists.

Before you invest any money in mining enterprises it will pay you to consult Capt. Albert Johnston (Mining Engineer) at North Bay, Ont. P.O. Box 548.

I have had over twenty-five years experience in nearly all kinds of mining work. I am the owner of several Silver, Gold and Iron Properties that I am willing to dispose of at a very low price.

For further information write to the above address mentioned.

SITUATION WANTED

Book-keeper experienced in all branches of mine accounting is open for position. Best of references.

Box 500, Canadian Mining Journal
Confederation Life Bldg., Toronto.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

Province of Nova Scotia

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver, $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

SULLIVAN CLASS "S" DRILLS

remove cores up to 500 feet, and are so light and compact that they may be operated in any part of a mine—yet built so strongly and of such fine materials that they give as accurate results as the largest diamond drills made. The "S" is suitable for surface as well as underground work. It may be driven by air, steam, belt, or electric motor.

SULLIVAN DIAMOND DRILLS are more widely used for testing mines and mineral lands than any other prospecting drills made, because they remove a solid core from all rock formations penetrated, from soft coal or rock salt to the hardest ores. They will bore holes at any angle and to any depth, and will remove cores of any desired diameter.

The JEFFREY
26-B "SHORTWALL"
ELECTRIC COAL CUTTER

For room and pillar work on the Longwall plan.

It cuts faster, consumes less power per cubic inch of coal cut, occupies less space, permitting the props to be set closer to the face of the coal,

is more easily controlled, operated and handled, is simpler and has greater strength, motor power and endurance

than any other make of
SIDE CUTTING MACHINE.

This machine is loaded' unloaded, moved to and from the coal face and in fact handled throughout by its own power.

HIGH GRADING.

In the early days of the Yukon gold excitement gold stealing was known to be prevalent and was winked at. The rich creeks of Eldorado, Bonanza, and Gold Run were particularly notorious as fields of operation for gold thieves. We have been credibly informed that in four years not less than eight or ten million dollars worth of gold was taken from these spectacular workings by persons other than the owners.

The gold mines of Nova Scotia have yielded more gold than shown by official returns. Many of the gold veins of the province are noted for the beauty of the specimen gold that they contain. In the palmy sixties hundreds of ounces found their way out of the mine by unauthorized channels.

The purloining of amalgam from the battery plates of stamp-mills is another prevalent variety of misappropriation.

As indicated before in the "Canadian Mining Journal," silver stealing has assumed serious proportions in Cobalt. Assertions to the effect that high grading is carried on to the extent of more than thirty thousand ounces per month, were received at first with incredulity. But, while it is impossible to estimate precisely the toll exacted by the silver thief, there is strong evidence, both direct and indirect, that the case has not been exaggerated.

Apparently the playful habit of enriching oneself at the expense of a mere mine owner is looked upon as an excusable failing. It is time for this point of view to be corrected.

Gold stealing and silver stealing are unqualified theft, and justice demands that the thieves be punished promptly and efficaciously.

Unfortunately our statute books do not provide effective means for bringing high graders to justice. Strong representations, however, have been made to the Minister of Justice at Ottawa and it is believed that the necessary Federal enactments will be promulgated before the close of this session. If the matter is laid over until next session it will be the duty of all the mining provinces to make a combined effort towards clearing up the situation.

A NOTEWORTHY DISCOVERY.

The world's production of tungsten ores amounts to only four thousand tons, and this in spite of a growing demand. From Queensland and the United States comes the principal supply. The prices paid are not constant, owing largely to the fact that much of the ore is mined in isolated districts where the miner has

little chance to avail himself of the best market prices. But usually the price per unit ranges between $5 and $10 per unit for ore carrying sixty per cent. of tungsten tri-oxide. Hence, the mining of tungsten ores is nearly always profitable.

There have been discoveries made of wolframite and scheelite in Nova Scotia, British Columbia, and Ontario, but heretofore the ores have not been found in commercial qualities.

Within the past few weeks, however, a vein of scheelite, four inches wide, has been opened near the gold mine of the Consolidated Mines Company of Canada, at Moose River, Halifax County, N. S.

The vein, which has been traced for five hundred feet, lies in a slate belt. Foot-wall and hanging wall are well defined. The vein is four inches wide and is composed of scheelite, accompanied, unfortunately, by a considerable quantity of mispickel. However, the ore, as mined and without concentration, shows 50 per cent. scheelite, and the separation of this mineral from the mispickel should be a matter of no difficulty.

In a forthcoming issue we shall publish a full account of this new find. Meanwhile we wish to emphasize again the fact that, even in a country as small as Nova Scotia, where mining has been an important activity for many years, there are unsuspected mineral possibilities. It is too true that nearly all the important mineral discoveries in the history of mining in Canada have been accidental. We have now sufficient knowledge of the geology and topography of our country to encourage systematic investigation. The chances taken by the uninstructed prospector can be largely eliminated by intelligent study, practical knowledge, and carefully constructed plans of campaign.

TECHNICAL WRITING.

On another page apears a review of Mr. T. A. Rickard's new book "A Guide to Technical Writing."

We regard the publication of this modest volume as an event both pleasant and significant.

For long Mr. Rickard has thrown the whole weight of his influence in the direction of reform. Once a flagrant sinner himself, according to his own frank confession, he has, with prayer and fasting, chastened and purified his style and diction. One result is that his writings are undoubtedly more widely read and more keenly enjoyed than those of any other writer on mining topics.

It is not possible, of course, to ascribe this pre-eminence entirely to carefully cultivated accuracy in the use of language. Perfection, whether on the printed page or in speech, is a pale thing. But Mr. Rickard's writings are neither perfect nor pale. They are spontaneous, vigorous, eminently readable, and accurate—humanly, not divinely, accurate. They have an inherent charm that can neither be acquired nor transmitted; but they also show the signs of careful workmanship.

Now the path of the reformer is a rocky one. He is usually mistaken for a prig or for a fool, and sometimes he is both.

But the author of this bold and diminutive volume is neither a fool nor a prig. He is a mining engineer. He has wrought in mining fields all over the world. His wide knowledge of mining men and affairs has been honestly gained and earnestly absorbed. He writes as a mining engineer to brothers of his own profession. And he is worth listening to.

If, then, an experienced and cultivated writer feels deeply the need of purifying current technical literary usages, of cutting out what is spurious and superfluous, of cleaving to that which is simple, of choosing that which is correct, it is surely not too much to expect of younger and inexperienced writers that they will seek to avoid the open pit-falls of error and bad taste.

In all seriousness, loose, sloppy writing is inexcusable. Mining men are, for reasons into which we need not enter, painfully prone to carelessness in this direction. A little care, a little thought, the exercise of a little sound common sense would show offenders the justice of Mr. Rickard's strictures and the importance of his mission.

We earnestly hope that "A Guide to Technical Writing" will find its way into every Canadian mining camp and into every Canadian mining engineer's office.

THE GYPSUM INDUSTRY OF NOVA SCOTIA.

The gypsum deposits of Nova Scotia are one of that province's large assets. During the year 1907 the quantity of gypsum quarried was 332,345 gross tons. With the exception of a few thousand tons calcined and manufactured into plaster in the province, the whole of this output was exported to the United States.

The value of crude gypsum to the Nova Scotian operators is about one dollar per ton. It is shipped to the various points in the United States where a duty of 50 cents per ton is imposed. The manufactured product is sent back to Canada where it pays a duty of 12½ cents per ton.

Were all the gypsum produced in Nova Scotia calcined and manufactured before exportation the province would gain considerably more than one million dollars per annum.

This statement is strengthened by the fact that Nova Scotia and New Brunswick supply all but a fraction of the gypsum imported by the United States.

The analogy between the gypsum of Nova Scotia and the copper and nickel of Ontario is complete. Both provinces are losing millions annually by exporting raw material instead of finished products.

The Halifax Chronicle makes a strong plea for the assistance of the Federal Department of Mines in giving adequate publicity to the extent and importance of the maritime gypsum deposits. We take it that this is a reasonable and seasonable request. The first duty of the Department of Mines is to give its services to those branches of the mineral industry that most need it and that, in the opinion of those competent to judge, will give a suitable return for effort expended.

Examination of statistics leaves no room for doubt as to the assured future of the maritime gypsum industry. The enormous known deposits in Nova Scotia and New Brunswick, and the exceptional facilities for mining transportation, and marketing, provide ample foundations for large expansion.

INDUSTRIAL.

We commend to the attention of our readers the matter published in the "Industrial Section" of the "Canadian Mining Journal." From our advertisers and other manufacturing concerns, we receive from time to time illustrated descriptions of new and improved types of machinery. Whilst all of this material is frankly submitted for direct and indirect advertising purposes, there is often highly valuable technical information included.

All such special articles, when of sufficient interest to merit publication, will be grouped in our "Industrial Section." The sources drawn upon are not confined to those firms whose names appear on our advertising pages. Whilst, naturally, these contribute matter most regularly, yet notices and special descriptions reach us from many other manufacturing concerns. These we use as opportunity offers.

The central idea of such a department in the Journal is the segregation of anything that smacks of advertising. The pages used are never, under any consideration, sold as advertising space. But the open distinction signified by the title "Industrial Section" marks them as being in a class by themselves and gives us the opportunity of using excellent material without the danger of lowering the general tone of the Journal.

PRINCE EDWARD ISLAND.

The smallest province of the Dominion does not appear in the list of mineral producing countries. It is rich agriculturally, and its shore fisheries are not inconsiderable. But there are no mining activities throughout the length and breadth of the fertile island.

But now, after due weighing of geologic evidence, the Dominion Government has decided that Prince Edward Island is a fair field for prospecting. Therefore the strata that underlie the tight little province are to be explored in the hope of finding coal.

The Island's situation geographically might justify the use of the word "expectation" instead of "hope."

EDITORIAL NOTE.

The Russian Government is contemplating a new State monopoly in platinum. Russia produces about seven tons of the metal annually. Most of this amount is exported to the United States and Germany. The effect of a considerable increase in price would have a serious effect upon the electrical industries. The search for platinum in Canada should be encouraged.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

By F. W. Gray.

Article II.—The Mines of the Glace Bay Basin. (continued)

Reserve Colliery (No. 5 Colliery, Phalen Seam).—Reserve Colliery obtained its distinctive name from the fact that it was originally opened to work a concession reserved by the Provincial Government for the purpose of encouraging the building of a railway from Sydney to tap the mines of the Glace Bay Basin. This work was undertaken by the Glasgow & Cape Breton Coal & Railway Company, who were afterwards reorganized as the Sydney & Louisburg Coal & Railway Company, under which company Reserve mine was worked until it was absorbed into the Dominion Coal Company's properties.

The first shipments from Reserve are recorded in 1872, when the mine produced 27,802 tons, followed by a production of 63,300 in 1873. During 1874 to 1877 the conditions of the coal trade were so bad that operations were practically suspended. From 1878 to the present time, however, Reserve mine has been a consistent and steady producer. Since the opening of the mine in 1872 about 9,500,000 tons have been produced, of which amount 8,000,000, or 84 per cent. of the aggregate, has been mined under the direction of the Dominion Coal Company since 1893.

The coalfield has ben worked through three main haulages, namely, the French Slope, Main Slope and East Slope, all of which proceed from the outcrop of the Phalen Seam. The Main Slope was closed at the end of 1894, its territory being exhausted. The East Slope rope will shortly be taken off, when the haulage will be limited to the French Slope. This slope is 12,-

Reserve territory, which is the barrier against the work-000 feet in length from the bankhead to the end of ings of No. 2 Colliery. An auxiliary electrical haulage plant has recently been installed at No. 8 Landing, at a point 9,000 feet below the bankhead. This trip haulage will deal with all the coal below that point, and will transfer to the endless main haulage by means of a curve. The power for the trip haulage is generated at

Dominion, No. 3.

the Central Electric Plant, and is conveyed down a borehole 420 feet deep to a 100 h.p. Westinghouse motor.

The old main haulage engine was a large engine originally intended to drive the shafting of a large cotton mill, and it operated three haulages by means of friction clutches on a common shafting. It has recently been dismantled and replaced by one of the 28 inches by 60 inches engines from No. 1 Colliery.

The surface power equipment consists of seven Babcock & Wilcox boilers with rated capacity of 1,678 h.p., fitted with Parsons blowers. There are three steel and one brick smokestacks.

The air compressor house contains two Rand Compressors, steam cylinders 36 inches by 20 inches by 48 inches stroke, with a capacity of 3,000 cubic feet per minute, installed in 1900; one straight line Norwalk compressor with a capacity of 2,000 cubic feet, installed in 1905. In 1906 a Walker compressor was added, having a capacity of 3,500 cubic feet. This compressor is of similar design to the four other Walker compressors that the Coal Company have installed. It is compound, steam cylinders 24 inches by 41 inches, air cylinders 23½ inches by 38 inches, with 48 inch stroke, running at 60 revolutions. The whole of the compressor plant is lubricated by an automatic lubricating installation, similar to the arrangement at the other collieries. The operation of the automatic lubrication is economical in the consumption of oil, and is much more cleanly and less dangerous to the enginemen than the previous oil-can method.

The mine is ventilated by two fans, one situated near the bankhead at Reserve, and the other at the mouth of the East Slope, about one mile distant. This latter fan is of the Guibal type, 24 feet diameter, vanes 6 feet 6 inches wide, running at 100 revolutions, with an original rated capacity of 300,000 cubic feet at 2 inch WG. There are two small boilers at the East Slope which generate steam for the fan engine. The ventilator at Reserve itself is a Chandler fan, 15 feet diameter, with a rated capacity of 205,000 cubic feet at 1.4 inches WG.

The bankhead is new, and was erected in place of the old structure that was destroyed by fire in October, 1906. This old bankhead had grown by successive accretions, and was a wonderful maze of screens and machinery, as such erections usually are. The present structure is of wood, hard pine posts with spruce stringers on concrete foundations, completely housed from the weather, and fitted throughout with stand pipes and hose for fire protection.

The screening plant consists of four sets of screens and picking belts, arranged to deal with the product from the Phalen and the Emery seams. At the present time Nos. 1 and 2 belts deal with the French Slope Phalen coal, No. 3 belt with the East Slope Phalen coal, and No. 4 with the Emery coal. When the East Slope is discontinued Nos. 3 and 4 belts will deal with the Emery output, which is steadily increasing.

The coal from the French Slope, after leaving the haulage rope, is conveyed by an inclined automatic car-haul to a Phillips automatic dump, which unloads on to a feeder belt 7 feet 6 inches long by 4 feet wide speeded at nine feet per minute. This belt discharges the coal gradually, with the minimum of breakage, and well distributed on to a battery of three shaking screens, which in turn discharge on to a picking belt, 38 feet 6 inches long by 5 feet wide, running at sixty feet per minute. The picking belts are well manned by young men, whose business it is to throw out any shale or foreign matter that is detrimental to the quality of coal, which is an easy matter owing to the even distribution of the coal layer and the slow movement of the picking belt. The other three belts are of similar construction, being 40 feet, 52 feet 6 inches, and 54 feet in length respectively. Each set of picking belts discharges on to a transverse loading belt, 39 feet long by 4 feet wide, driven by a 15 h.p. electric motor. The end of the loading belt can be raised or lowered according to the amount of coal in the car being loaded so as to limit the fall to a minimum and reduce the breakage. The screens and picking belts are driven by a 75 h.p. motor, and there is a separate motor for the car haul. Power is obtained from the Central Electric Plant.

The mouths of both the main and back deeps of the French Slope are protected by reinforced concrete ap-

Concrete Approach to the French Slope Reserve.

proaches, installed after the bankhead fire. That in the main deep is 90 feet in length and the back deep 30 feet.

The colliery shops are very complete, in order to render the colliery more or less independent of the central shops at Glace Bay. The machine shop contains a crank-shaper, 12-foot lathe, Merrill pipe threader and other machine tools, driven by a small Sturte-

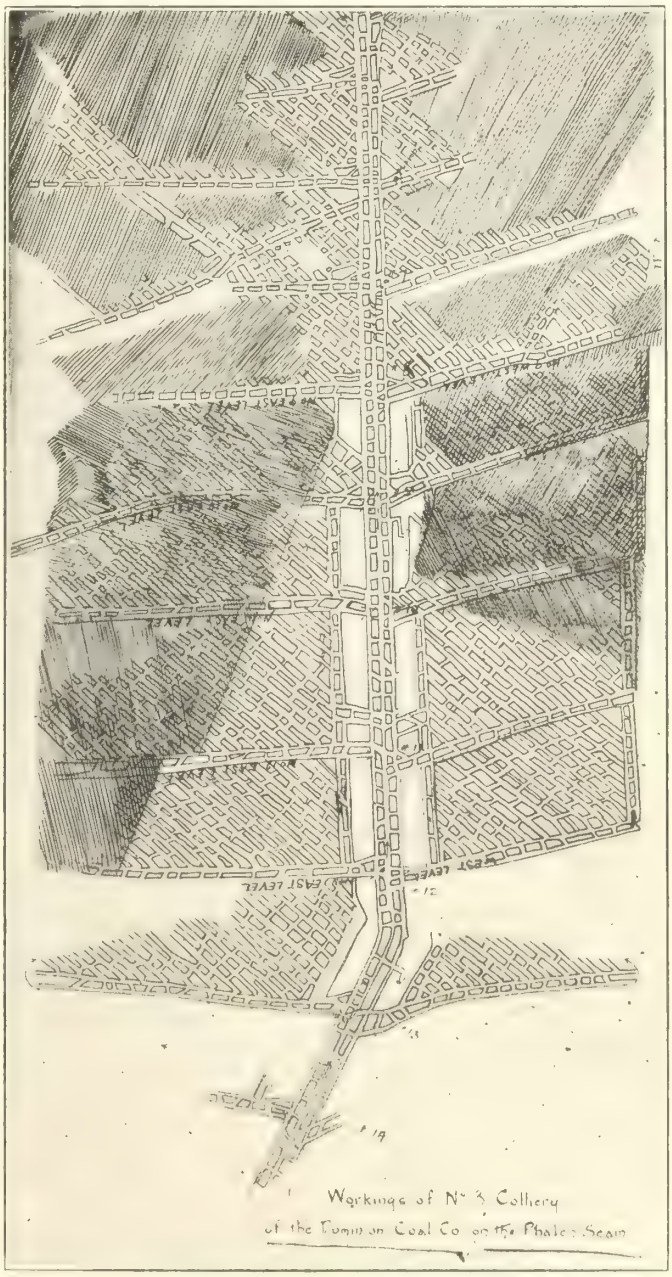
vant vertical engine. There is also a carpenter and blacksmith's shop with a steam hammer for machine pick sharpening.

There are two lamphouses, one at Reserve, which serves both the Phalen and the Emery seams, and one for the East Slope side of the mine. They are fully equipped with automatic lamp filling and cleaining machinery, and with the Ackroyd & Best safety lamp, which was referred to in a previous notice. There are altogether about 1,200 lamps at this colliery, some 400 of which are in use in the Emery seam.

The mine has the usual complement of mining machines and shearers, and is equipped throughout, both above and below ground with fire hose, chemical extinguishers and water connections on the air lines.

The number of men on the payroll is around 600. At present the mine is double-shifted, and will probably remain so. Reserve Colliery was always a big producer, and on double shift has produced 800,000 tons in one year. The present policy of the Dominion Coal Company is in favor of single shift, as in many collieries the extra tonnage obtained is not always commensurate with the additional labor cost that double shift necessitates. Although it may be taken as a rule in all collieries that increased tonnage mean decreased

Dominion No. 3—Bankhead Approach.



working expenses, yet there are circumstances when large outputs mean anything but economical mining.

Since the bankhead fire the Coal Company have spent a great deal of money around Reserve, and with its well designed bankhead, its new ring fence and the generally neat and trim way in which the surface is kept, the old colliery bears quite a rejuvenated aspect. Outside the fence is the colliery office and store, and near to the office is the fireman's hall, which will shortly be equipped with several Draeger apparatus as an auxiliary to the central rescue station.

Reference will be made more fully to the workings of the Emery seam at this colliery, in a subsequent notice.

No. 3 Colliery.—No. 3 mine is a slope mine occupying that portion of the Phalen coalfield lying between the territory of Caledonia Colliery on the eastern side and Reserve Colliery on the western side. The mine was opened in 1889, and commenced to produce coal in 1900, since which time it has put out 2,750,000 tons of coal, in round figures. The capacity of the mine at the present time is about 36,000 tons per month, on double shift.

The workings of No. 3 Colliery are typical of those of the other mines on the Phalen seam, and the plan accompanying this description will serve to give a fair idea of the methods of working which have been generally adopted in the Phalen seam. The pillar and stall method, or "stoop and room" is used exclusively, with the exception of a small section of No. 6 Colliery. Rooms are driven 20 feet wide, and the size of the pillars left will average 25 feet by 60 feet in No. 3 Colliery. As the workings go to the deep the pillars have of course to be left sufficiently large to withstand the greater strata pressure. This is a matter to which in late years the Dominion Coal Company have devoted particular attention. The inadequate pillars left in

past years have caused the loss of much coal, but the good methods pursued by the Coal Company in this matter are well exemplified at No. 3, where the pillars are being drawn systematically in retreating order outbye from the barrier, and no coal is being lost in the second working whatever.

The territory of No. 3 consists of an oblong piece of clear coalfield, without any disturbance. The main haulage road is laid out on full dip, the pitch being about 7 per cent. The levels are spaced every 450 feet,

and substantial pillars, 100 feet by 450 feet have been left, affording adequate protection to the main roadways. The compactness of the mine, its freedom from water, and the workmanlike layout of the underground workings, have combined to make No. 3 an economical and consistent producer, and it is one of the few mines that do really well when double shifted. It is generally referred to in genuine Canadian idiom, as a "pretty nice little proposition."

The chief difficulty at No. 3 has been its long haul. At one time the endless haulage was 11,500 feet in length, which meant the handling of 23,000 feet in 1⅛ inch wire rope. The haulage is now divided into two sections. The upper haul is 8,000 feet in length, and is effected by means of a 22 inches by 42 inches hoist situated near the bankhead. There is an overground haul of about 4,500 feet from the mouth of the slopes to the bankhead, occasioned by the fact that No. 3 bankhead was originally designed to deal with the output from the Phalen and the Emery. The Emery slope, which is quite close to the bankhead was ultimately abandoned. The lower haul is effected by means of an electrically driven auxiliary haulage situated at No. 7 landing, supplied by power from the central power station, the transmission cables being carried down a borehole to a 200 h.p. Westinghouse motor. The present length of the lower haul is about 4,000 feet. The rope used is 1⅛-inch crucible steel in both cases. The mine cars have a capacity of two tons, and the track is 30-pound rails on wooden sleepers.

The surface plant consists of three Babcock & Wilcox boilers rated at 54 h.p. There is one large Walker compressor, compound type, steam cylinders 31-inches by 57 inches, air 32 inches by 51 inches, stroke 60 inches, running at 55 revolutions, with a capacity of 6,000 cubic feet per minute. The air pressure on leaving the compressor is about 75 pounds, and is delivered at the face at about 65 pounds. Some idea of the amount of air pipe that is needed in a machine pick mine may be gathered from the fact that No. 3 mine, which is a small one, has 12,000 feet of 8-inch pipe, 7,000 feet of 4-inch, and 30,000 feet of 1½ and 2-inch pipe.

The mine is ventilated by a 13 foot 6-inch Capell fan, having a capacity of 200,000 cubic feet at 2-inch wg., directly conected to an 18-inch by 18-inch Taylor-Chandler engine. The fan is substantially erected with steel and concrete housing. It is situated at the mouth of the slope, and has a separate small steam plant. The air current is carried direct from the fan a distance of 7,200 feet to the bottom of the deeps, air crossings being built over every landing, and is split at the face of the deep, returning up the main haulage road. The main intake is used also as the travelling road.

The mine water is very small in quantity, and is dealt with by two air-driven Cameron pumps 12 inches by 18 inches, which discharge through the Caledonia barrier at No. 7 level. The water is pumped at the Caledonia water shaft.

The bankhead is a wooden structure, approached by an inclined trestle, the return wheel of the endless haulage being situated at the rear end of the bankhead. The coal is dumped by two rotary Jenckes tipples, on to a feeding belt, over a triple shaking screen battery thence by means of a thirty feet picking belt to the cars. The bankhead has three tracks, for slack, nuts, and screened coal. The screening plant is driven by steam, and the colliery has its own independent electric lighting plant.

The colliery buildings are the usual ones, wash house, lamphouse holding 600 A. & B. safety lamps, warehouse, etc. There is a fireman's hall with hose reels and fire fighting apparatus, which will shortly receive several Draeger aparatus.

No. 3 Colliery is situated in a well wooded bit of countryside, and it is one of the pleasantest of the colliery villages. The miners' houses are built in well spaced blocks of two. Each house contains five rooms,

Type of Miners' Houses at No. [illegible] Colliery

and pantry, and they rent at $6 per month. The management has succeeded in making their workmen "houseproud," and with its whitewashed fences, freedom from unsightly garbage and its surrounding greenery, No. 3 approaches what a colliery village should be from an aesthetic and sanitary standpoint. The management and the citizens of No. 3 are to be congratulated on their public spirited initiative and their regard for those little decencies which make life in a colliery district worth living, and the lack of which is apt to lead to the reign of "shackdom" and dirt.

(To be continued.)

On recently fusing a little tantalum powder, Siemens and Halske placed it in a kind of Crooks' tube instead of an electric furnace. On the anode the metal powder received the bombardment of particles from the cathode, and was quickly fused. A magnet deflected the tiny stream of bundles, and made it act upon any desired part first of the mass of metal exposed at the anode.

To determine when wire hoisting ropes have depreciated beyond the limits of safety has been a difficulty of mining engineers, and to avoid risk—in the absence of exact tests—many ropes have been doubtless discarded while still in fairly good condition. The strength of the ropes is now gauged by a novel use of electric induction. The ropes are passed through a coil of copper wire traversed by an alternating electric current, and the variations of induced current—which exactly correspond to changes in the thickness of the rope—are recorded on a suitable instrument. Dangerous wear or broken strands cause the indicator to give warning.

VALUATION OF MINING PROPERTIES.

By George H. Gillespie, M.E.

(*Continued from last issue.*)

The profitable lifetime of a mine is an important feature, in that the investment must be returned within the period of the lifetime.

Should a property be purchased at, say, $500,000, and $100,000 be spent on plant, equipment and development, and the resultant net earnings be 20 per cent. per annum, or $120,000, on the total investment of $600,000, this would mean 5 per cent. interest on the investment and 15 per cent. towards return of capital. At the end of seven years the capital invested in the venture would be returned plus interest. It could hardly be considered that the return of capital plus 5 per cent. is a fair return for the risk of the venture. Therefore a higher earning power, or a much more extended lifetime must be looked for to justify the purchase of a property at such a price. The extension of the profitable assumed lifetime would depend largely upon the natural location of the mining property under consideration, a seven years' continuous profitable lifetime for a mining proposition being rather the exception than the rule. Such a price could only be justified by the actual presence in the mine of assured ore at the time of examination to give a production for seven years as indicated, and the extended lifetime or increased earning power could be justified by the indicated probabilities of the mine ahead of development. It would be safe to assume a reasonable continuity of conditions beyond the point of development, based upon conditions found in the actual ore reserves which had been developed. Provison would have to be made for additional development and working costs caused by increased depth, and in many cases for capital charges for re-equipping surface plants to admit of working at increased depths or on a larger scale.

In the case of the valuation of a silver mine in which the valuation of the ore reserves has been done with reasonable accuracy, but on the market price of silver of a year ago, let us suppose a mine in which $5,000,000 worth of silver ore is blocked out on four sides.

Silver has decreased in value 20 per cent. and the purchase price is $4,000,000, based on values of silver at date of examination.

$5,000,000—Value ore reserves a year ago.
1,000,000—Depreciation.

4,000,000 - Gross value at present prices.
400,000—10 per cent. silver values, smelting charges.

3,600,000
480,000—Annual operating charges $160,000, and cost of mining, etc., for annual gross output of $1,500,000.

$3,120,000.

Therefore, allowing a reasonable working capital in proportion to purchase price, say $500,000, the total investment would be $4,500,000, and against this we would have to-day assured net assets of $3,120,000 approximately. Should these net assets be the result of development to the 300 foot level, and should all conditions be favorable, it would be reasonable to assume that the second 300 feet of depth to be opened up would give ore reserves approximating in value to the first 300 feet. Of course additional working capital and working costs may have to be charged up against the opening up and working of this new ground.

$4,000,000—First block 300 feet.
4,000,000—Second block 300 feet.

8,000,000
800,000—Smelting charges.

7,200,000
1,000,000—Five years' operating expenses.

6,200,000
1,000,000—Interest charges at 5 p.c., 5 years.

$5,200,000

That is, operating this mine for five years to give a gross output of $1,500,000 per annum, at the end of five years the capital invested would be returned plus 5 per cent., and the mine worked out to the 600 foot level, leaving the ground below the 600 foot level to earn the real return for the risk of the venture. This would pre-suppose a continuous average profitable lifetime down to the 900,, 1,200 or deeper levels over a long period of time.

The case above has been that of a small vein or veins of exceedingly high grade silver ore where the gross output is large for a small tonnage of ore.

The fluctuations of the market affect a mine of this nature more than would be the case with a large low grade body of silver ore. The small high grade ore body will usually have a much shorter lifetime. Should it be operated during periods of low priced metal, it has a shorter lifetime in which to look for recovery in prices. Large low grade mines, having a longer lifetime, have a much better chance of good average market prices of products.

The purchase of a property for development, when the development must be spread over a period of years, such period being a period of non-productive operation, must be affected by the fact that capital so expended plus purchase price is losing interest so long as the mine is non-productive. Such loss of interest must be added to the final amount of capital to be returned from the operation of the venture. This feature is of course not alone confined to mining, but is common to most investments in ventures that call for gradual bulding up. In mining it has a greater influence on the problem, when it is considered, as has been already stated, there is only a certain definite ore body from which these charges and commensurate returns on investment must be won.

General.

Mining property that has been properly valued presents one of the best possible fields for investment. My own fixed belief is that the part capital should play in mining is that of creating industrial conditions, and not the purchase of golden but doubtful probabilities.

There is always the chance that a mine will turn out better than the facts observable appear to warrant. This is always the hope of the purchaser, but I do not believe that it would be wise or fair to pay higher prices for this chance. The more nearly mine valuation can be brought to the ideal of engineering which is a science based on facts, the better.

There are, of course, many problems of mine development that call for large expenditures and that are often speculative at their inception. The undertaking of such operations is often legitimate engineering, but I do not think that it is wise to pay large purchase prices for the privilege of taking such risks.

FLUORSPAR.

Abstract of Advance Chapter, Mineral Resources of the United States for 1907, by Ernest F. Burchard.

Character and Occurrence.

Fluorspar or fluorite, chemically calcium fluoride (CaF_2), consists of calcium and fluorine in the proportions of 51.1 to 48.9. The mineral is crystalline, only slightly harder than calcite, and consequently crushes easily. It crystallizes in the isometric system, and is commonly found in cubes. In color it is often white and opaque, although it ranges from a clear, slightly bluish, glasslike substance, through various brilliant shades. It is usually pure, running 98 to 99 per cent. calcium fluoride. Material carrying less than 95 per cent. finds little sale.

Fluorspar has a wide distribution geographically, but in only five States, Arizona, Colorado, Illinois, Kentucky and Tennessee, have deposits been exploited. It is also secured as a by-product of lead and zinc mining in Albemarle County, Va.

Practically, wherever it has been mined, fluorspar occurs as a vein material, although under widely different conditions. In the Kentucky-Illinois district it is the chief mineral of value in many of the veins, lead and zinc being of secondary importance, while in the Castle Dome district of Arizona, jig concentrates of fluorspar are made incidental to concentrating.

Preparation and Uses.

The various uses of fluorspar depend on its chemical composition, fluxing properties, and phosphorescence when heated, and on its optical and gem-like properties. Its preparation involves separation from other minerals, the treatment comprising hand-sorting, crushing, and jigging. Part of the high grade ore is ground and shipped in barrels and sacks; the rest is sold in lump form. Its separation from zinc blende is difficult, but has been accomplished by means of flotation in dilute solution of aluminium sulphate. This basic flotation process is now in successful operation at Marion, Ky. Shallow pans, in which mechanical stirrers are operated are the essential of the equipment.

The principal classes of consumers, in order of importance are, smelters and metallurgists, makers of opalescent glas and enamelled wares, and chemical manufacturers. The highest grade, "American lump No. 1," which runs less than 1 per cent. silica, and is white or clear pale blue in color, is sold either ground or in lumps to the two last classes of consumers. The grinding of the pure, clear spar can be dispensed with for some purposes, as it readily decrepitates to a powder when heated. The second grade, "American No. 2," is used in the production of ferrosilicon and ferromanganese, and in basic, open hearth steel furnaces to give increased fluidity to the slag and to reduce the contents of phosphorus and sulphur. This grade includes colored spar and may run as high as 4 per cent. silica, though most of it is sold with a 3 per cent. guarantee. The lowest grade, "gravel spar," including all that contains more than 4 per cent. silica as well as spar mixed with calcite, is used in iron and brass foundries. Its use makes the metal more fluid and permits the use of greater quantities of lower grades and scrap by carrying phosphorous, sulphur, and other impurities into the slag.

Although flourspar possesses higher quantitative efficiency as a flux than limestone, especially in smelting refractory ores, it can only be used in limited quantities. In England and on the continent the use of fluorspar is more common than in America. Its minor metallurgical uses are in the extraction of aluminium from bauxite, in smelting gold ores, in refining copper, and in refining lead bullion. In the latter process it is first converted into hydrofluoric acid.

Fluorspar is also used for bonding emery wheels, for carbon electrodes to increase their lighting efficiency, and as a constituent of Portland cement.

Production and Prices.

In 1907 the total quantity of fluorspar marketed was 49,486 short tons, valued at $287,342, a gain of 8,690 short tons in quantity and in value, $43, 317 over the output for 1906. This indicates a firm condition in the fluorspar industry, since there was on hand at the close of 1906 a stock of 13,470 tons, which has evidently been absorbed without leaving quite so large a surplus on hand at the close of 1907. Gravel spar was valued at $4.47 per ton; lump spar at $7.51; and ground fluorspar at $10.31 per ton. Small quantities of lump spar were reported to have sold at $18 to $35 per ton.

Up to October, 1907, the demand was generally strong, with prices ranging from 75 cents to $1 in advance of those of 1906. Toward the end of the year there was a decided faling off in production as a result of the depression in the iron and steel business.

Wholesale prices in December, 1907, in domestic lump spar f.o.b. shipping point, ranged from $8 to $10 per long ton; on ground spar, from $11.50 to $13.50 per long ton; and on foreign crude, ex dock, from $8 to $10 per long ton. In May, 1908, the quotations were exactly the same.

The fluorspar imported into the United States is said to come largely from English mines, the competition being felt principally along the Atlantic coast.

A new plan for storing gasolene or petrol depends upon the fire-stopping property of wire gauze that gives safety to the Davy mining lamp. A gauze tube is inserted in the opening of the can or tank, extending to the bottom, and the orifice is then sealed up by a plug held in place by fusible solder. If fire occurs near or around the tank, the solder melts and the plug is blown out, when the vapor escaping through the gauze tube burns quietly without explosion. In a test of the method, twelve out of seventeen ordinary cans filled with volatile oil exploded on contact with fire, throwing the burning liquid in every direction, but twelve cans fitted with the safety device failed to explode and the liquid burned quietly and harmlessly.

A Contribution to the Discussion on the Genesis of the Graphite in Argenteuil and Labelle Counties, in the Province of Quebec.

By F. Hille, M. E.

I arrived almost post festum at the meeting of the Canadian Mining Institute that was held last March in Ottawa, having been delayed by the lateness of the trains; the result of this was that I missed the reading of Mr. H. P. H. Brumel's paper on "The Modes of Occurrence of Canadian Graphite."

I now have before me the printed report of his contribution and of the discussion which followed it, as given in the Quarterly Bulletin of the Institute, and find them extremely interesting, not only from an industrial standpoint, but also from the view of economic geology.

The broad discusion of the subject especially impressed me as demonstrating that the members of the Institute are taking a keener interest in these matters, by offering, every man his quota, towards the solution of the phenomena of the origin of ore deposits.

In my own opinion there is no study more fascinating than the quest for a solution of the problems as to how or by what processes the different minerals are deposited in the various rocks in which they are found. And when we look over the field, and are confronted by the observation that in almost every locality we find some degree of dissimilarity or certain distinct features in the occurrence of even one and the same mineral, it is but natural that we should encounter problems, that multiply in proportion as our investigation extends from country to country.

Notwithstanding this, nature has given us certain basic rules upon which we can build the foundation towards a solution of her riddles.

While I was reading Mr. Brumel's paper and the opinions that were expressed by the different members regarding the genesis of graphite, it occurred to me that it might be of interest to offer a hypothesis, which, in my opinion, appears to correspond more strictly to the field evidence than some of those which were brought forward during the discussion.

I wish to take this opportunity of reviewing these hypotheses again, in order to bring them afresh into my readers' minds, and in order to call more particular attention to those points which, to my mind, seem to weaken their probabliity of affording a correct solution.

Four theories were brought out in the paper and in the later discussion.

1. That propounded by Mr. Brumel, the leaching of the "original rocks" thus freeing them of carbon, which was subsequently redeposited as graphite.

2. That of Mr. Coste,—the deposition of the graphite by volcanic emanations, in the form of hydro-carbons.

3. That of Mr. Cirkel—idiogenetic occurrence with the enclosing rocks.

4. That of Dr. Woodman,—which hints at an organic origin.

Let us consider the first hypothesis. Mr. Brumel presupposes that some "original rocks" had contained carbon, and the silicious and other waters had leached out the carbon and redeposited it into the gneiss and along the contact and fissures of the eruptives. He does not state what he implies by the "original rocks." If he means by this term the oldest rocks, then we must regard it as referring to the gneiss as such, he himself calling this an archaean rock. Next in point of age we must consider the limestone, then the diorite, granite, felsite and lastly the diabase. Are these latter Mr. Brumel's "original rocks?"

If we were to make use of microscopic examination, I doubt much whether we would discover in the eruptive rocks last named, with the probable exception of the diabase, even the slightest traces of graphite; had these been the vehicles that carried the carbon we would still expect to find a certain amount of carbon yet in the rocks, it being inconceivable that the solutions should have leached every particle out of the rock.

Mr. Brumel makes the further statement that the contact of these eruptives with the limestone showed only silicate of lime, and with the gneisses, sulphate of lime; this would signify that the granite emanations carried principally silicates, while the diorite carried more sulphates. If, however, these intrusives had contained carbon, their point of contact with other rocks, (the veins excepted, which were produced by a later incident), should undoubtedly show carbon also, in some form or other. I am exceedingly curious to learn in what form the carbon existed in these original rocks, in order to allow it to submit so readily to the leaching process by silicious and other—perhaps sulphurous—waters. It is not to be expected that hydrocarbons would be found deposited in an eruptive rock, at least not until it is cooled, and we are almost compelled to believe that, on account of the intrusion of the four later eruptives, the rocks must have retained an intense heat for a very long time. More than this, a combination of carbon and sulphur could hardly be obtained in the manner suggested, and even granting that this were possible, the resulting combination, CS_2, or CS, would be so unstable a compound that in its course of travel through the fissures and cracks of other rocks, it would seek an exit by the best and shortest outlet to the surface—and then where would the graphite come in?

This hypothesis seems to me to be extremely unconvincing, until some further light is shed upon several of the points.

2. The second theory attributes the production of graphite to a process of injection of hydro-carbons into the openings of rocks other than that from which it came. There is, perhaps, a possibility that something of this nature may have taken place, but in order to ensure the complete success of the process suggested in this hypothesis, we must presuppose the active presence of three important factors, viz., (a), the meeting and combination of emanating carbon with similarly hydrogen, in a somewhat cooler portion of the vent through which they were seeking an outlet to the surface. (b), The condensation of these hydro-carbon vapors and their deposition into the yet cooler fissures, of various sizes, of the different rocks, and, (c), ultimately the conversion of this mineral into graphite, by considerable heat, produced, either by the last of the erup-

tive rocks, or by intense pressure, without the admission of air or oxygen, in fact, I might say, almost in a vacuum. That hydro-carbons are produced by such a process as I have described is certain, but it is, without doubt, a very delicate one, to produce graphite from them by eliminating the hydrogen from the carbon without evaporating both elements. In addition to this, the statements that were made above, regarding the continuous heat produced by the rapid succession of divers eruptives, still holds good here, and this goes to show that hydro-carbons could not have long remained in a state of condensation in these rocks, as this condensation could only have occurred at a time when the diorite, granite, and felsite had cooled sufficiently to permit it.

3. The third hypothesis supposes that the graphite might have been deposited at the same time as the constituents of the gneiss, and that this rock is a sandstone, not an eruptive, and that the graphite could not have been taken up by it in a disseminated condition. And the further opinion was advanced that the graphite had not been deposited as such, but as an "original mineral," and later converted into its present state.

In reply to this let me say: Mr. Brumel, at the beginning of his paper brought to our attention the fact that the graphite was found in the Archaean rocks; if this be the case, then we have to deal, not with a metamorphosed sandstone, but with a Laurentian gneiss of volcanic origin, and somewhat altered and shattered, in situ, by the later intruding or extruding rocks. Were this rock of sedimentary origin the microscope would soon inform us of its true nature. On account of the stresses which it underwent, it became pervious to the inflow of vapors and fumes, especially under pressure, just as a porous sandstone would, as may be shown by the different secondary minerals contained therein. Why a sandstone should not absorb these volcanic products I fail to see, for we must not lose sight of the fact that there are porous sandstones, crushed sandstones and also impervious sandstones.

Let us now consider why the claim that the graphite might be an idogenetic product with the sandstone cannot be supported by field evidence. First, take into consideration only the enormous time that must have elapsed from the beginning of the formation of a sandstone of such considerable extent to the time of its solidification, and again to the period of the eruption, first of the basic and later of the acid type of rocks, and lastly, to the time of the diabase eruption—a decidedly long period of time indeed! Now we have seen that there are graphite deposits of all descriptions, in and in contact with these younger eruptive rocks, graphite, very pure and of crystalline structure. Whence did this portion come? Was there a constant supply of this carbon furnished over this long period, sufficient, not only to satisfy an immense deposit of "sandstone," but also to fill the fissures in rocks of a much later age over a very considerable area? Another matter upon which I would desire to be enlightened is what are we to understand by an "original mineral of carbon" that is deposited together with the constituents of a sandstone, and changed later into graphite. If it is not a volcanic emanation product, then it must have had an organic origin. There is, however, no basis for our supposing the existence of organic life in archaean times, and we are thrust back to the conclusion that, after all, it must be a carbon originating from the only source from which we could expect that element to be derived, viz., a plutonic source. For these reasons I do not think that this whole hypothesis is tenable.

4. The remarks contributed by Dr. Woodman to the discussion on the paper are the only criticism which introduces the organic origin of carbon, especially as regards the second of the examples which he quotes. The first instances cited by him are not sufficiently elaborated and explained to give us a definite picture of the geological features of that district, nor is there any elucidation of how the black slates arrived there, or what is their nature and composition, whether clay-slates or the remains of former volcanic ash-beds. His second example has no possible connection with the subject of Mr. Brumel's paper, which is dealing solely with a graphite occurrence in veins and impregations in an Archaean rock stratum, in which there was not the remotest possibility of the formation of organic coal beds. The only service rendered is perhaps to show in how many different ways graphite might be formed.

I will now, with the reader's permission, explain my own views as to the manner in which these graphite deposits came into existence in the localities under consideration by Mr. Brumel.

Before taking up the origin of the graphite itself, it is necessary for us to take into consideration the manner in which the receptacles, that is the openings, fissures and cracks, in the different rocks were formed, and in what sequence.

We have already seen that the gneiss is the oldest of the series, and next probably comes the limestone, then following in regular order the diorite, granite and felsite, and last of all the diabase. Now it is obvious that the fissures in the gneiss and the limestone were produced by the eruptive rocks which followed later, the fissures in the diorite by the granite, felsite and, perhaps also, the diabase, while the contact fissures were the result of either the stresses accompanying the eruption of each successive rock, or of the contraction of these eruptives as well. A portion of these fissures in the gneiss and limestone was filled by the silicates of the granites and the sulphates of the diorites; there is, therefore, no evidence to show that either the diorite or the granite have contributed to the origin of the graphite. There is now only one crack left to which we have to look for the parentage of the mineral in question, and this is the diabase. There is every probability that here, as we find in so many other localities, the trap rock was the original source.

I have had opportunities of examining a large number of graphite deposits in the archaean and post-archaean rocks, and in every case I have been able to trace their origin to the diabase, and the principal basis of proof rested upon the fact that this rock itself carried in some cases considerable, and in other cases appreciable amounts of this mineral.

We find in this locality a number of deposits of graphite, although they are of no great extent and the mineral is somewhat impure; we find further a number of diabase dykes, being the plutonic facies of exposed laccolites, which are heavily saturated with graphite; we have several diabase craters and numerous dykes, nearly every one of which shows more or less graphite; in the immediate vicinity of some of these trap dykes we find a number of small nests of anthraxolite; we have also a large area covered with the co-called "black slates," which are merely solidi-

fied ash-beds, the exhalations or explosion products of our diabase volcanoes, and these contain, in places, a large percentage of graphite.

I also observed graphite deposits and incrustations along the trap rocks in the American Rockies, which I visited last year, and have met with a similar occurrence in different parts of Europe, but after all, these instances which have come under my personal observation, are insignificant as compared with the many similar occurrences of which we have knowledge that are scattered throughout the world.

Let us now consider how we can account for the origin of the graphite in the localities here under discussion. Mr. Brumel mentioned the fact that in several places the graphite is found in contact with the diabase, but very little importance was given to this rock in the course of his paper, the reason for this being, probably, owing to the outcrops being rather infrequent, and the graphite deposits in contact with it being of no great commercial importance. However, we ought not to overlook the fact that the diabase occurs not infrequently in the form of immense laccoliths, and that sometimes only a few small apophyses are found breaking through to the surface, or have been exposed by the erosion of the overlying strata. Let us accept this as having occurred in the locality in question, and suppose that the vapors and fumes of this laccolith, composed of carbon as well as other constituents, had been compressed into the fissures and fractures of the rocks above named, where they were retained in a condensed form as graphite. Just as from a volcano there are poured forth, with tremendous force, ashes including particles of graphite, in combination with steam and other gaseous elements as an explosive and triturating vehicle, so also could graphite, with gases as the carrying agents, be injected into the smallest interstices and crevices of the rocks. Again, if we grant that it is possible that a magma, injected into any rock strata, can carry graphite almost to saturation, then we must also admit the possibility not only that this carbon escaped from this magma, with other gases, but also that such gases found an outlet from some source at a far greater depth, and were deposited in a cooler stratum in the form in which we find them there to-day. The fissures which we now find on the surface might have been at the time that this deposit was injected, in a stratum hundreds, or even thousands of feet below the former surface of the earth, and they may be regarded as vents which had attained a certain degree of temperature favorable to the deposition and retention of the graphite.

The explanation that I have given above is perhaps the simplest possible of the genesis of the Quebec graphite, being based upon phenomena with which most of us are, or should be quite familiar, but we usually are only too apt to seek for our solutions of the processes of nature by piling hypothesis upon hypothesis, a method that only results in irritating us, and eventually carries us farther and farther away from the goal we seek.

The processes of nature's laboratory are, after all, simple enough, if we only endeavor to study them patiently and read them correctly, but this cannot be done in our studies, nor can the knowledge be acquired from books. No, indeed; rather should we go out and, as it were throw ourselves into nature's arms and allow her to show us the products of her laboratory, pick up every little stone and mineral, piecing them together like the pattern of a mosaic, and resolving them into one harmonious whole, and the result will always be a beautiful and perfect picture.

THE TECHNICAL ANALYSIS OF MAGNETITE, HEMATITE AND LIMONITE.

By R. Bolling.

In the Sydney district all of the above minerals are reduced to pig iron in the blast furnaces located at South Sydney and Sydney Mines. About 600,000 tons of ore are smelted annually. Systematic sampling and analysis are of course necessary from a metallurgical standpoint as well as for the computation of the bounty donated by the government to foster the steel industry in Canada.

Sampling.

There is no royal road to securing a representative sample of a cargo of iron ore. Some experience in this business is perhaps the best teacher, in fact, the I. C. S. schools at Scranton, Pa., who will teach and guarantee a position in any line from a "showcard writer" to that of mining engineer are silent on the subject of sampling. It cannot be taught, even by mail. It must come from personal observation and has to be learned on the spot. Fresenius tritely remarks in the preface to his "Quantitative Analysis," "the larger the sample, the more accurate the analysis," but adds "the smaller the sample, the sonner the analysis will be finished." It is well to steer a medium course in taking samples. My practice is to take 20 pounds from a railroad car and 200 to 500 pounds from steamers.

Crushing.

Jaw crushers working on the Blake principle are satisfactory on hard lump ore. They must be driven by power. All of the sample should be crushed to pass a half-inch sieve. The sample, if heavy, should be worked up in sections, in the quartering operation. The simplest method of mixing preparatory to quartering is to throw the mass of ore in the centre of a large rubber cloth blanket. This is then held by the corners by two men and a rolling and oscillating motion imparted to the sample. Results are very satisfactory as regards uniformity of the mass.

Drying.

Moisture must be accurately determined. The sample quartered down to from 5 to 50 pounds depending on the original sample, is weighed in flat copper receptacles, and dryed on a steam table to constant weight.

Grinding.

There is only one kind of machine that was ever intended for grinding iron ores, this is the ball mill. Its work is perfect. Large mills with drums 20 to 30 inches should be used. They must be "rinsed" out with the ore from a discarded quarter of the sample to be ground, before applying the power.

Agate Mortar Fine Grinding.

Sample from the ball mill is bottled and a small portion, 5 to 8 grams, ground in the fine mortar, until it feels free from grit.

Preliminary Tests.

Spread the ore powder on a glass plate and draw the poles of a horse shoe magnet over. If it attracts entirely it is magnetite, if partially, it should be treated as magnetite, if not at all it is either hematite or limonite. Heat a small portion in hard glass test tube, if limonite, moisture condeses on the cool walls. These tests will indicate the kind of ore, whether magnetite, hematite or limonite. They also decide the method of treatment. Magnetites are only partially soluble in hydrochloric acid, whereas hematite and limonite are completely soluble except in rare instances.

Getting the Ore in Solution.

This is an important step in its analysis. More low results come from neglect or inexperience at this point than from awkward manipulation. You can never feel easy in your mind if little black specks are seen after the ore is supposed to be dissolved. Begin right and the analysis will be finished much quicker. It is no use attempting accurate analysis if the agate has not been rubbed long and hard. It is not pleasant, but repays the grinder in mental satisfaction afterwards.

Magnetite.

Fuse 5 grams of ore and 15 grams of sodium carbonate (dry) in a large 60 c.c. platinum crucible with lid, for thirty minutes over an air-gas blowpipe. It is better to start the fusion with the air shut off for the first few minutes and then gradually increase the air blast to the maximum. Cool and place in a large 500 c.c. porcelain casserole and heat on the electric hot plate or other hot metal surface, adding 400 c.c. of HCl, 1.10 sp. gr., to dissolve the fused mass and covering with a clock glass. After a short time the crucible can be examined and if no fused material is cemented to its sides it can be removed and rinsed off with water. Having taken out the crucible and its lid, the casserole is allowed to stand on the plate until nearly all the acid is evaporated, then cautiously moved to a cooler part and there watched while it evaporates to dryness. Heating must be continued until every trace of HCl is driven off.

Limonite and Hematite.

Fusion can be dispensed with if .5 grams of ore are weighed into a 500 c.c. casserole and heated with 400 c.c. of HCl, 1.10, in the same manner as described for the magnetite sample. The sample can now be treated in the exactly the same manner, viz.: The residue dissolved with 50 c.c. HCl, 1.20 sp. gr., diluted with water and the silica separated by filtration. The filtrate is caught in a 500 c.c. volumetric flask and, after washing with dilute acid and hot water, the silica is removed from the filter, ignited in a platinum crucible and weighed, the weight divided by 5 and multiplied by 100 gives the percentage of silica. The contents of the volumetric flask are now brought up to the mark with cold water, a rubber stopper inserted and the contents thoroughly mixed. With pipettes measure into appropriate beakers, 100, 125 and 75 c.c. of the ore solution, and proceed thus: The 100 c.c. and 125 c.c. portions are evaporated down to near dryness and strong nitric acid added, then evaporated a second time and finally a third time. Phosphorus is determined in the 100 c.c. portion by the well known molybdate precipitation and titrated with nitric acid solution, after solution in standard caustic potash, of a strength of about .00014, or thereabouts of phosphorus. The alkalimetric method of estimating phosphorous is very simple and exact. Two solutions of acid and alkali are balanced against each other and then standardized against a standard steel or pig iron.

The beaker with the 125 c.c. portion is now diluted with water, transferred into a liter flask, zinc oxide emulsion added to precipitate the iron, mixed, and 500 c.c. filtered off through cotton, heated to boiling and titrated with decinormal $KMn\ O_4$ solution, 1 c.c. equivalent to .0016 gram of manganese. This is Volhard's method and for simplicity and accuracy it can be recommended.

The beaker with 125 c.c. portion is transferred to a one liter beaker, neutralized with ammonia, sodium acetate solution added and iron, alumina and phosphorous precipitated by boiling. Filter, and wash with hot water, and boil up with water and wash again to free precipitate from all soluble salts. To filtrate add bromine water and then ammonia, warm on hot plate a few hours and filter. To filtrate which must be boiling, add hot ammonia oxalate and filter off lime, titrate the precipitate with $K\ Mn\ O_4$ solution, each c.c. of the decinormal solution being equal to .0028 gram lime. The filtrate from the oxalate precipitation is evaporated to small bulk, 100 to 200 c.c. cooled, and magnesia precipitated by microcosmic salt, after addition of 25 c.c. of ammonia. Filter and wash with 10 per cent. ammonia, ignite and weigh as $Mg_2\ P_2\ O_7$, and calculated to Mg O. The precipitate which now contains all the phosphorus, iron and alumina, is dissolved in hot dilute HCl, and diluted to 500 c.c. neutralized to just acid with ammonia, 10 grams sodium thio-sulphate and 1 gram sodium phosphate added and the solution boiled for 20 minutes. The aluminium phosphate is then filtered off, ignited in a porcelain crucible and weighed as $AlPO_4$ and calculated to Al_2O_3. One hundred c.c. of the ore solution is now drawn by pipette, run into a 300 c.c. flask, reduced with granulated zinc for two hours, acidulated with a little dilute H_2SO_4, filtered into a large flask and titrated with decinormal $KMnO_4$ solution, each c.c. of which is equivalent to .00056 gram of metallic iron. The remaining 100 c.c. of ore solution is evaporated down to 50 c.c. and 5 c.c. of 10 per cent. barium chloride added just after boiling, and the sulphur precipitated as $Ba\ SO_4$ and filtered and weighed after ignition.

There are the usual determinations made in iron ore analysis and for routine work will be found to give accurate checks when run in duplicate. Combined water can be determined by heating one gram of ore red hot for 30 minutes, weighing and dividing the weight of water loss by 1, multiplying by 100, giving

the per cent. The only novelty about the famous Wabana ore from Bell Island, Newfoundland, is the fact that it carries traces of vanadium. Some of the imported Spanish ore, namely, Carthagena, carries a little galena. The other ores are native and Swedish of great purity.

WORKING COSTS OF MINES, AS PRACTISED ON THE RAND.

By John A. Dennison, Member.

(Paper read before the Institute of Mining and Metallurgy.)

Mining is essentially a commercial business and therefore should be conducted on lines which approximate as closely as possible to the recognized forms of established businesses.

Accounts are kept for four principal reasons:

First.—For the convenienec of the manager of the mine, who naturally has to follow the cost of each department closely.

Second.—To enable consulting engineers and controlling firms to see the cost of each branch of work, both on the surface and underground, with a view to cheapening or improving such work.

Third.—To supply Government with statistics.

Fourth.—To enable the mine owner or shareholder (who frequently knows little about mines) to see how his business is progressing, the amount of profit made, or the dividend he is likely to receive.

"Simplicity" in mine accounts should be aimed at, as it means less staff, less cost, and renders the accounts more easily understood by the owner of the business, i.e., the shareholder.

The following notes touch on the main controversial points in working costs of gold mines, particularly on the Rand:

Capital Expenditure.—All initial expenditures on machinery and plant, buildings, dams, shafts, development, head-gears, etc., up to the time of crushing is of course capital expenditure, from money provided generally from working capital shares or loans. Any surplus working capital that there might be would soon be spent in completing the plant, and in improvements. The trouble arises after the plant starts producing, when all the working capital is exhausted, how to deal with the further expenditure on similar items which goes on more or less during all the life of the mine, i. e., whether to charge it to capital account or to working costs. If the items are large (duplication of mill, new vertical shaft, new cyanide or slimes plant), and the necessary money is raised by a new issue of shares, debentures, or special loan, such expenditure is generally considered capital expenditure. But if the items are smaller ones occurring and recurring during the life of the mine, and are paid out of the profits, the mine owner or shareholder will, so far as he is concerned, consider them "working costs," i. e., as the difference between the revenue and the net profits he receives. It does not really matter much to the shareholder how the expenditure out of the revenue is allocated, so long as he can see at once by glancing at the monthly or annual reports how much net divisible profit has been made. So that in such reports it is essential that when some of the expenditure is charged to capital account the working costs and profit should not be shown alone, but the capital expenditure and net profit should also be shown.

The ideal method, and perhaps the simplest (though only adopted in a few cases) is to close all capital accounts when the plant is complete and running, and the original working capital is exhausted; and not to re-open them except for special expenditure of money specially raised.

Working costs naturally vary in different countries, on different fields, and also on the same fields; in the latter case, owing to relative size of plant, hardness of rock, dip and thickness of reef, etc., But many managers are more or less driven by directors or the public to show low working costs, as it is unfortunately often considered that low working costs mean good management, whereas of course they often mean poor policy, and slightly higher costs might result in additional net profit.

Such pressure, however, whether direct or indirect, often drives a manager to charge as much as possible to capital account, and as little as possible to working costs, both for his own sake, and sometimes possibly for "window dressing," in order to show a large working profit. Each manager has his own ideas as to what constitutes capital expenditure, and sometimes managers differ very widely in their methods and ideas.

Looking at a mine again as a commerical business, it seems necessary or advisable that "working costs" should in some way reflect the amount of capital exneded, either through "depreciation" or interest and redemption of loans, etc. The prevalent practice, however, seems to be not to include "depreciation" in working costs, even when it is allowed for, but to write it off "premium on shares" account, or some other equally useful account, so that it does not directly show in costs. It therefore follows that costs of 20s. per ton may be very good if only £500,000 have been spent on equipment, etc., but very high if £1,000,000 have been spent. The consequence of the usual practice of making no allowance for depreciation or redemption of capital in mine costs is that it is often impossible to see how much real profit is being made; in fact, in cases where working capital shares have been issued at a premium the profits or dividends often seem large on the nominal capital, but would be much smaller on the total amount of money raised for working capital, and still smaller if on the total amount spent, including capital expenditure out of profits, which in time amounts to large sums. Sometimes, indeed, if the whole expenditure were considered, the "profits" shown would not be sufficient to redeem the capital, much less pay interest on it. Curiously enough, money spent on capital account is often looked

upon as additional working capital raised, i. e., that interest on and redemption of such money must be allowed for before the additional plant can be correctly said to have produced any additional profit.

Capital Expenditure.

Capital expenditure on the Rand may be divided into two groups:

1. Initial expenditure to bring a mine to the producing stage.

2. Subsequent expenditure.

1. The initial expenditure may be divided into four headings:

(a). Property Account.—No depreciation is allowed for this in balance sheets or working costs; and it stands at its original cost right through the limited life of the mine, though the exhaustion of ore makes it less and less valuable.

(b). Machinery and Plant, Buildings, Dams, etc.—In some cases depreciation is written off every year to premium on shares account, or appropriation account, in other cases not at all, it being considered that as the money has been spent in bringing the mine to the producing stage, depreciation of the account would mean the creation of a cash reserve and payment of smaller dividends, if it had to be debited to profit and loss account.

(c). Shafts.—All initial expenditure on vertical and inclined shafts is left as an asset in the balance sheet, i. e., neither depreciated nor redeemed.

(d). Development.—In the largest group of mines initial expenditure on development, i. e., sufficient to bring the mine to the producing stage, is not written off, depreciated, or redeemed at all, it being decided to keep ore reserves to this or a higher level by current development, which is charged direct to working costs.

In many other mines this initial expenditure on development is debited to what is practically a capital suspense account, and is used for calculating current development redemption rates, eventually being redeemed during the last two or three years of the mine's life.

In other cases—by fixing the rate of redemption slightly above the average cost—this account is gradually extinguished, after which the ore reserves form an asset for which no credit is taken, and all current expenditure on development goes to working costs.

As regards—

2. Subsequent capital expenditure, i. e., after the milling stage is reached, there are many methods employed, and each mine management has its own ideas as to what constitutes capital expenditure. Any new expensive machinery, increase of plant or buildings, or new shaft, is charged to capital account, all repairs and renewals being charged to working costs. Sometimes a manager is given an allowance of £500—£1,000 per month (chargeable to working costs) for renewals of machinery and plant, and he has to make this sum do; this is a good arrangement in some cases, but it breaks down when any heavy expenditure is necessary. Some mines on the Rand have at times closed their capital accounts altogether, all further expenditure being charged to working costs; but most of them have at later dates re-opened the capital accounts for various reasons.

The chief trouble is in regard to inclined-shaft sinking, cutting stations, driving, winzing, raising, cross-cutting, box-holing, etc. In one large group of mines all such expenditure is called "development" and is charged to working costs monthly, care being taken to spend as far as possible an equal sum every month sufficient to keep the ore reserves up to a fixed standard (2—3 years ahead of the plant), and generally to increase the total tonnage gradually. This system deserves consideration, as it is the simplest, and gives the shareholder the clearest idea of the position.

Another favorite system on the Rand is to consider all current sinking of inclined shafts, cutting stations, and sometimes main cross-cuts, as capital expenditure, and not as "development." In such cases only the costs of driving, winzing, raising and box-holing are considered to be "development," and these are debited to a separate capital account, which is practically a suspense account.

At stated intervals, the total sum standing at the debit of this account, say £150,000, is divided by the total tonnage of milling ore estimated to be developed (after allowing for sorting out waste), say 1,000,000 tons, and the resulting figure of say 3s is charged to the next month's woking costs per ton milled. In many cases this figure is altered monthly, according to the rough estimates of tonnage "developed" by driving only, i. e., each foot of driving is calculated to develop a certain tonnage acording to length of "backs," etc.

Some mines carry this system farther, and eliminate from the calculation the milling ore obtained from development drives, etc., thus redeeming monthly only the portion of tonnage milled which came from the stopes. Even this is not strictly accurate, as it does not allow for the sorting out of some of the development rock.

The aim of this system of development redemption is, of course, to charge to the working costs of one month only the correct and fair proportion of the development expenses. The result is that, in pushing development ahead, a huge capital suspense account is created, which will doubtless be liquidated at the end of the mine's life.

The advantages of this system are obvious; the chief objection to it is that, even on the Rand, there is a considerable amount of poor and unpayable ore in the total ore reserves upon which the redemption rate is calculated, so that the payable ore, or the ore milled, is redeemed at the average cost of developing payable and unpayable ore together. It is admittedly difficult to calculate, even approximately, the total tonnage developed monthly, and still more difficult to calculate correctly the paying tonnage.

At annual valuations, corrections of 50,000 tons are occasionally made, and a large tonnage of developed ore is sometimes lost through caving-in stopes. Even on the Rand, blocks of ore which appear to be payable from development asays, are often found to contain a large proportion of unpayable rock. Certain standard factors, such as the percentage sorted out, stope widths, dip, etc., are used for the monthly calculation of tonnage developed, but the actual figures frequently differ from the standard ones.

It does not, therefore, appear safe to calculate development redemption on a strict mathematical basis, and, in my opinion, the rate adopted should not only be the total expenditure divided by the probable tonnage of payable ore, but should also allow a considerable margin for safety, thus gradually extinguishing the development capital account.

As regards Shaft Sinking and Main Cross Cuts: I submit that the cost of current work after milling starts should be included under the heading of "development," and be dealt with in the same manner. Theoretically, perhaps, in a mine with a defined boundary line in depth, the last 100 feet of shaft sinking, say from the 23rd to the 24th level, should be charged against the tonnage developed by that footage, and the 100 feet between the 22nd and 23rd levels would be charged half to the ore between these levels, and half to the ore between the 23rd and 24th levels. Thus the lowest or 24th level ore would have to bear a proportion of the cost of the whole shaft down to the 23rd level, as well as the whole cost between the 23rd and 24th.

For example, supposing an incline shaft cost £30 per foot for 2,400 feet, levels 100 feet apart, the ore developed down to the 1st level would be debited with only 1-24 of the cost of the 100 feet of shaft, viz. £125, the remaining £2,875 being charged to a capital suspense account, while the ore in the lowest 100 feet of the mine would have to bear the cost of 100 feet of shaft, viz., £3,000, plus its proportion of 2,300 feet, viz., £8,325, on a total of £11,325.

Even this large total would be insufficient, as the cost of sinking increases somewhat with depth. The impossibility of calculating the exact length the shaft will reach, and estimating whether payable ore will be found all the way down, even if lateral boundaries are parallel and the width of reef constant, preclude the acceptance of this method, in its entirety at least; and the consequent separate suspense accounts involved for the ore developed by each level would lead to hopeless complications.

Note.—This system might be possible on the Rand, but would naturally be impossible for ordinary mining where the ultimate depth of the shaft is quite unknown.

Therefore, it seems more advisable that the cost of sinking the incline shaft from the surface, or from the bottom of the vertical shaft, to the first level should be borne entirely by the ore developed by that level (obviously such ore could not be developed without it), and the next 100 feet charged to the second level ore, and so on. Here again the book-keeping involved would be far too complicated; the money has been spent, however little or much ore may afterwards be developed from it, and therefore the system of charging the whole cost of current shaft-sinking direct to development and to working costs seems the best and safest; unless, perhaps, one charges out a sufficient average sum per month to pay for a year's shaft-sinking.

As regards Additions and Renewals to Machinery and Plant, beyond ordinary maintenance, after the initial plant is completed, the system adopted should depend upon whether the money is provided out of profits or raised separately. If raised by means of an issue of shares, it would doubtless be considered capital expenditure, and in some cases depreciation would be charged somewhere in the balance sheet or appropriation account, but, according to present practice, would not show in working costs.

If the money is raised by an issue of debentures or a loan, under the present system the interest is sometimes charged to working costs, but generally to an appropriation account, and the redemption of the debentures or loan is not shown in working costs. The result of this system is that capital expenditure goes on year after year, especially in directions that will show any decrease in "working costs"; the decrease generally follows, but as the costs contain no portion of the extra expenditure it is almost impossible to tell whether the saving in costs has been sufficient for the interest and redemption of the additional expenditure.

Personally, I think the system of a monthly allowance in working costs for additions to plant and machinery is in most cases the best, provided this allowance is used as a fund which is only overdrawn in exceptional cases. If by this means the plant is maintained at full value there would not appear to be the same necessity for depreciation.

Depreciation.

Depreciation on original machinery, plant, buildings, etc., is a very vexed question. Generally speaking, companies whose head offices are in London are compelled by their auditors to write something off annually for this, but it is rarely shown in working costs. Companies with head offices in the Transvaal and elsewhere seem to do more as they like, and frequently no depreciaton is written off.

Profits Tax.—This is never included in "working costs;" there seem to be many reasons which can be adduced for and against this system.

Stores on Hand.—This item in the balance sheet should include only such stores and spares as are suitable for current requirements. All accumulations of discarded appliances or deteriorated stores should be written off every few months, the loss being charged to "working costs" in average monthly instalments. As it now stands the depreciation on this item in many cases is in reality very large, and should, I submit, always be charged to working costs. In Australia, I believe, a representative of the auditors personally checks the stores on hand annually, and this seems in some respects the best method; but as far as I am aware, no valuation by outside parties takes place in the Transvaal, California or Colorado.

Suspense Accounts.—Some few mines manage to do without these accounts (which are never disclosed in the monthly or quarterly reports issued to shareholders, and are very rarely disclosed clearly in annual reports), but on the majority they seem to be regarded as necessary evils, and at times they are almost unavoidable. Annual payments for fire insurance and licenses, as well as recruiting fees for native labor, etc., are generally charged to suspense accounts and working costs debited monthly with a proportion. They are also used for sundry repairs, small renewals, conveyor belts, etc., and frequently amount to large sums, which are partially liquidated when an exceptionally good month affords an opportunity

Such accounts are very useful and are perhaps allowable under strict supervision, but the ideas of managers differ very widely as to the items debited to these accounts and the time allowances for repayment. The object is, of course, to show regular working costs as low as possible. At times, when inspecting mines, I have had some difficulty in ascertaining the full amount of such suspense accounts,, especially when, owing to a complicated system of dual control, some of the accounts are kept at the mine and some at the head office; but they often account for some of the difference between the published monthly profit and the improvement in the cash position.

Gold Reserves.—Most of the Transvaal mines have kept a certain amount of undeclared gold in reserve during the past few years with a view to showing regular outputs; at times these reserves have amounted to as much as 10,000 or 20,000 ounces, not kept at the mine, but realized by the bank in the ordinary way, credited to the general account, and in many cases the money has been spent. The legality of such a course has been questioned, and some mines have now abolished the system; others continue it, but publish the position of the reserve at the same time as the monthly or quarterly "profits"; and a few retain the original system of undeclared gold reserves, though the present tendency is to abolish the system. Without touching on the legality or propriety of the system I would point out that it leads to many regrettable complications in the accounts and reports.

The figures relating to value of ore milled, percentage of extraction, yield per ton, etc., in the manager's monthly or quarterly reports, are necessarily inaccurrate by the amount of the reserve added to or taken from the output, and actual results have to be modified to suit a policy of averaging. This practice considerably reduces the value of the published figures for comparing current results. A statement of the amount of the reserve gold at the annual meeting does not help a shareholder to gauge the real profit in any one month or quarter. Sometimes the value of ore milled and yield per ton only are altered, sometimes only the extractions and yield per ton; sometimes all three; so that it becomes difficult at times to follow the actual results.

Directors and consulting engineers therefore do not always get the actual figures which are necessary for a close scrutiny of mining operations, and are sometimes confused by the methods they themselves allow; and even managers have been known to be inconvenienced by the two different sets of results. On would think that the gold reserve would have to be shown in the annual report; but this difficulty was in some cases got over by including it in the item of "sundry creditors."

In addition to the above, there are of course minor elastic methods of regulating declared outputs, such as "cleaning up" cyanide works, etc., a few days earlier or later, occasional steaming of battery plates, reserve amalgam, and small rich patches of ore kept in reserve underground for assisting the output during the latter days of the month; but these items only occur at rare intervals, and do not amount to very much. It sometimes happens, too, that dividends declared for a certain period are facilitated by the fact that they are not payable until a month or so after the period has ended.

Head Office Charges.—These are sometimes included in working costs where the head office is near the mine, say in Johannesburg; in other cases they are not so included. This is a frequent cause of difference in working costs. Sometimes the management expenses, salaries of manager and consulting engineer, etc., are included in general charges under working costs; sometimes they are given separately.

Realization of Gold.—On the Rand this item of cost is frequently debited to gold account, the net yield only being shown the lowest possible in monthly and annual reports, thus showing the lowest possible working costs. In many other cases it is charged as a separate item or under general charges to working costs; and in one case it is deducted from the yield in monthly reports and included in working costs in the annual report.

There are many arguments for both systems, but from a mining point of view it seems very advisable to keep the proceeds of the sale of gold quite distinct from all charges, otherwise it affords no guide to the value won from the ore, and does not compare with the extractions.

From a commercial point of view, too, it would appear advisable to include it in working costs, otherwise one cannot easily see the cost of different methods of realization and the extra expense due to distance from recognized markets, nor the loss or gain due to the very varied fineness of the bullion shipped.

One of the results of all this straining after regular yields and proofs, and making a fetish of low working costs, is seen in the fact that annual dividends only amount to 70 to 80 per cent. of the monthly declared profits of the Transvaal mines, presumably to some extent also on other mines.

It seems impracticable to lay down rules for guidance as to how the smaller details of working costs are to be kept in mines all over the world, as the conditions vary so much on different fields and in different mines on the same field, and according to the metal mined. Questions such as the method of pay-tickets, the points where the surface tramming begins and ends, the allocaton of power and labor costs, etc., are all dependent upon local conditions. Moreover, the books of Messrs. A. G. Charleton, Nicol Brown, Prof. James Lawn, and others, give ample guidance in regard to detailed systems that are advisable when they can be adopted.

My idea is that the Standardization Committee might think it wise to confine its questions and ultimate recommendations to principles and large systems such as I have outlined, rather than enter upon an endless discusion of minute details which would be still more difficult to bring into line. It may be argued that most of the points referred to herein are matters to be settled by boards of directors and auditors rather than by managers or consulting engineers. It seems to me, however, that it is of vital importance to the latter to have their working costs kept in such a way that they can easily see the full actual cost of their operations on a commercial basis.

In most cases, too, the directors or financial committee allow a great deal of discretion to their managers or consulting engineers in these matters; and in any case the latter always have considerable influence which can be exercised in straightening out such questions.

Every manager would, I feel convinced, prefer his working costs to be kept on a simple inclusive basis, but for the continual demand, expressed or implied, for low "working costs."

Directors would also benefit by simplicity in costs, except for the glamor of low "nominal" costs and high "nominal" profits; and reports and cost sheets would be easier to grasp.

Shareholders, too, who after all are the owners of the mines, would much apreciate simple inclusive statements of working costs which they could understand In fact, the nearer the dividends coincide with declared monthly profits, the more pleased will shareholders be, as their usual way of adding up monthly declared profits and calculating on receiving the full amount in

dividends often lead to disgust; and anything which may prevent the ordinary shareholder from seeing clearly the actual progress of his venture is, I think, to be deprecated. In the long run, mining engineers and the mining industry can only suffer from such a procedure by the undue loss of public interest.

Up to quite recently the book-keeping and statistical staff of each mine on the Rand has been very large. In addition to statistics for the manager and each department head, endless statistics have to be prepared for the consulting engineer and the controlling firm, as well as for the government and Chamber of Mines. All of these entail expense, as the costs have to be allocated in order to fit each system. In fact, more than one manager has mentioned to me that the head office officials seem to consider that the mine ought to be run to suit the system on accounts instead of vice versa. There is now, however, in some quarters, an attempt to curtail some of the statistical work.

In contradistinction to this plethora of statistics, much might, I think, be learned from the systems in use on Californian mines. I visited one mine there (where a 60-stamp plant was in full swing) and noticed that one man acted as secretary, surveyor and assayer. The statistics kept were very simple, everything spent went straight to working costs and the latter were amongst the lowest in the State.

I would, therefore, again urge that, in making recommendations for the standardization of working costs, the objects to be aimed at should be simplicity, and that calculations of development, redemption rates, etc., should not be made to the third place of decimals, but that a large margin of safety should be allowed for the well known uncertainties of mining, even on the Rand.

In conclusion, I should like to state that, although for the purposes of the committee it has appeared advisable to mention some of the little inconsistencies and variations in the systems in use on the Rand, which I hope will be straightened out in time, yet I think it is agreed that mines on the Rand are more generous than most other gold mines in the amount of detailed information they give shareholders and the public; and I have so much admiration for the system of mine accounts and cost sheets in use on the best-regulated mines of the Rand, that I consider their system, with certain necessary modificatons, would form a useful basis for the standardization—as far as may be considered practicable—of mine accounts and cost sheets on gold mines throughout the world.

LIST OF THOSE TAKING PART IN THE SUMMER EXCURSION C. M. I. AS AT JULY 16, 1908.

Official.

Jas. Barrowman, Esq., Secretary Mining Institute of Scotland, Staneacre, Hamilton, Scotland.

Walter Johnson, Esq., (representing Iron & Steel Institute), c/o Messrs. Bell Bros., Middlesbrough, Eng.

Mr. Hugh F. Marriott, (representing Institution of Mining & Metallurgy), Mining Department, Messrs. Wernher, Beit & Company.

Wm. Frechevile, Esq., Past President Institution of Mining & Metallurgy (representing same).

John Ashworth, Esq., President Manchester Geological & Mining Society, Hanover Chambers, 8 King street, Manchester, Eng.

W. D. Wight, Esq., President South Wales Institute of Engineers, Park Place, Cardiff, Wales.

Prof. Dr. H. Potonie, Gross-Litchterfelde-West, Potsdamerstr, 35, Berlin, Germany.

W. H. Head, Esq., Sub-Editor The Mining Journal, 46 Queen Victoria street, London, E. C., Eng.

Louis Detrez, Esq., President L'Association des Eleves des Ecoles Speciales, Liege, Belgium.

Unofficial.

Dr. Frank D. Adams, McGill University, Montreal, Que., Stage I.

Rodger Beck, Esq., c/o Wm. J. Rees, The Laurels, Swansea, Wales.

C. E. Bloomer, Esq., Shenstoneville, Hales Owen, Eng., Stages I, II, III.

Geo. H. Campbell, Esq., Toronto, Ont., Stages I, II, III.

Dr. Wm. Campbell, Department of Metallurgy, Columbia University, New York, N. Y., U. S. A., Stages I, II, III.

Thos. Carlisle, Esq., 26 Brown street, Workington, Cumberland, Eng., Stages I, II, III.

R. E. Commans, Esq., London, Eng., Stage I.

Sherard Cowper-Coles, Esq., Grosvenor Mansions, Victoria street, Westminster, S. W., Eng., Stages I, II, III.

Albert N. Entwistle, Esq., Royal Mint., Ottawa, Ont., Stage II.

Chas. Fergie, Esq., Dominion Coal Co., Glace Bay, N. S., Stages I, II, III.

Stanley G. Flagg, Jr., Esq., c/o Messrs. Stanley G. Flagg & Co., 242 N. 19th street, Philadelphia, Pa., U. S. A., Stage I.

John Hogg, Esq., Silverbank, Cambuslang, Scotland, Stages I, II, III.

Mark Hurll, Esq., 144 West Regent street, Glasgow, Scotland, Stages I, II, III.

D. B. Langford, Esq., c/o Messrs. Grindlay & Co., 54 Parliament street, London, S. W., Eng., Stages I, II, III.

Sam Mavor, Esq., 47 King street, Bridgeton, Scotland, Stages I, II, III.

J. C. Murray, Esq., Editor "Canadian Mining Journal," Confederation Life Building, Toronto, Ont., Stages I, II, III.

J. Obalski, Esq., Superintedent of Mines, Quebec, Que., Stages I, II, III.

W. J. Rees, Esq., The Laurels, Swansea, Wales.

Gordon McI. Pyke, Esq., Box 893, Montreal, Que., Stage III.

Walter Rowley, Esq,. 20 Park Row, Leeds, Eng., Stages I, II, III.

Nicholas Richardson, Esq., General manager North Atlantic Collieries, Limited, Port Morien, Cape Breton, N. S., Stage III.

Dr. Heinrich Ries, Department of Geology, Cornell University, Ithica, N. Y., U. S. A., Stages II,III.

A. Sinn, Esq., Bienne, Switzerland, Stages I, II, III.

Alcutt Smith, Esq., Hartley Hall, Columbia University, New York, N. Y., U. S. A., Stages I, II, III.

Sydney W. Smith, Esq., 76 Norroy Road, Putney, London, S. W. Eng., Stages II, III.

Andrew Watson, Esq., 21 Bothwell street, Glasgow, Scotland, Stages I, II, III.

C. McDermid, Esq., Secretary Institution of Mining & Metallurgy, Salisbury House, London, E. C., Eng., Stage I.

THE IRON ORES OF CANADA.

By C. K. Leith, University of Wisconsin, Madison, Wis.

(Ottawa Meeting of the Canadian Mining Institute, March, 1908.)

I hasten to disclaim intention of attempting a comprehensive discussion of all known Canadian iron ore deposits. While I have seen most of the principal deposits in Canada and Newfoundland, and others have been examined by associates and assistants, I cannot claim to have sufficiently detailed knowledge of a considerable part of them to warrant detailed discussion. tention will be called rather to certain general features of comparison of Canadian ores with the several types of deposits of the United States which have been more fully exploited and studied, and thus view the Canadian iron ore situation with a perspective not otherwise easily gotten. For the purposes of this discussion, the Newfoundland ores are included with the Canadian ores, because they are controlled, mined and largely used by Canadian interests. So far as is necessary, information will be drawn from the various careful descriptions of Canadian ores published by the Dominion and Provincial Geological Surveys or Mining Bureaus.

The classification of iron ore deposits we shall use is partly a new one based upon recent detailed studies of the Lake Superior ores and ores of the Western United States.

All metallic ores are derived ultimately from the interior of the earth, whence they are delivered by igneous eruptions near or to the surface, there to undergo various distributions and concentrations under the influence of meteoric waters and gases. The variations in composition, shape, and commercial availability of an ore are controlled by variations of conditions under which the ores have reached the surface and have been distributed. The variations have developed the following types of North American iron ore deposits:

(1) Magmatic Segregation Type.—Ores brought to the outer part of the earth in molten magmas but retained in them during crystallization, with the result that the ores form part of the rock itself, just as do the feldspar and other minerals. Such are the titaniferous magnetites, containing refractory silicates, and frequently sulphur and phosphorus, in deleterious quantities. While known in enormous quantities over North America—in Canada principally along the Lower St. Lawrence river, and in the Chaffey and Matthews mines of Lower Ontario—smelting is not beyond the experimental stage and they are nowhere used at a profit.

(2) Pegmatite Type.—Ores which are carried to or near the surface in magmas and are extruded from them, in the manner of pegmatite dikes, after the remainder of the magma has been partially cooled and crystallized. They are deposited from essentially aqueous solutions mixed in varying proportions with solutions of quartz and the silicates. To this class belong some, and perhaps all, of the magnetite deposits along the contacts of limestone and igneous rocks constitutting the greater part of the iron ores of the Western United States, and most of the magnetite ores of Vancouver and Texada Islands, and elsewhere in British Columbia. The assignment of the British Columbia magnetites to this type is based on a personal comparison of them with ores in Southern Utah believed to be of this type, the origin of which is discussed in some detail by Mr. Harder and myself in Bulletin No. 338 of the United States Geological Survey. The essential features of these deposits are their highly crystalline, magnetic character, their content of garnet, amphibole and other silicates, local abundance of sulphides and of apatite. The area of these deposits at the surface varies up to about 0.2 of a square mile. They are easily located by their outcrops or by the fragments strewn down the slopes, but it is not so easy to determine the shape and extent of the deposits when found, because of their extremely irregular association with wall rock. It is not safe to assume that they extend a foot beyond the zone of direct observation. Their vertical dimensions and shape and their mineralogical composition at depth are relatively unknown. Mining operations in the west on this class of deposits have not been extensive enough to determine these facts, such deposits having been mined principally in but few localities, at Texada Island, at Fierro, New Mexico, and in the Monterey and Durango deposits of Mexico. In the United States and Mexico certain similar deposits, but not all, have been found to take on pyrites and garnet with depth.

A small amount of ore has been mined from Texada Island. The better ore averages about 55 per cent. iron content, and from this down; much of it is below Bessemer limit in phosphorus, and sulphur is in amounts requiring roasting. Garnet and amphibole are both abundant, locally requiring hand sorting. Silica varies, inversely as the iron, up to about 11 per cent. All of the ore contains a small amount of copper, locally as much as 4 per cent. The shapes of the deposits are extremely irregular. Seldom do the widths exceed 100 feet. In depth they are best shown by a tunnel 300 feet below the surface which discloses ore with essentially the same width and composition as at the surface.

The ores on the west coast of Vancouver Island have had only a little development work done on them. They likewise vary widely in iron content; phosphorus is low, sulphur is usually high, silica varies up to about 26 per cent.

Making due allowances for lack of development and possible shallowness and change of character with depth, it is still certain that there is a large known tonnage available in British Columbia, which will be used when West Coast demands warrant the establishment of a local steel industry, instead of the importation of finished products from the east. There are indications that this time may not be far distant. While suffering somewhat from their composition, they are easily and cheaply mined, and being located directly upon the coast, will have the cheapest transportation. So far as the ores have been used only in the State of Washington, and the recent rapid development of the Northwestern United States suggests that their further immediate use will be in Washington, notwithstanding duty, at least until such time as sufficiently large ore reserves in this part of the United States become developed or until the population of British Columbia requires a steel industry of its own.

To the pegmatite type are provisionally assigned the ores of the Atikokan and Hutton districts, of Ontario,

where the magnetites have the mineralogical and chemical constituents of this class and show such intimate relations with greenstones as to suggest a direct derivation from them. They lack the bedded structures, characteristic of ores of class (3) to be described, though in the Hutton district the bedded iron formation rocks are also present. The extremely irregular association of the ore with greenstone makes it difficult to outline the deposit even a few feet in advance of exploration. The Atikokan deposits are high in sulphur, 2 to 5 per cent., requiring roasting. At Hutton the sulphur is low so far as explorations yet go, and phosphorus runs about 1 per cent.

To this class of ores also may belong at least a part of the magnetites in the pre-Cambrian Grenville series of New Jersey[1], some of the magnetites of the Adirondacks of New York[2], some of the magnetites in the Grenville series of Southeastern Ontario[3], and the magnetites of Cornwall, Pa.,[4] and Cranberry.[5]

These deposits have essential features in common and mineralogical and chemical similarities to the western ores of this class It may be that part of the Ontario Grenville ores belong rather with the following class (3), suggested not only by their characteristics, but by Dr. Miller's recent correlation of certain associated rocks with the Keewatin series of the Lake Superior region, which contains ores belonging to class (3).

The Grenville ores of lower Ontario are interbanded lenses of magnetite, gneisses and amphibolites, closely associated with, and partly in direct contact with, crystalline limestones of the same series. The ores vary from lean unworkable magnetite gneiss, carrying a small percentage of magnetite ribs as compared with gneissic ribs, to deposits of nearly pure magnetite. The iron formation bands are lens shaped and discontinuous. Their greatest width is probably less than 150 feet. They have been mined to a depth of 350 feet, but most of the workings are less than 100 feet. The better grade ores average much the same in iron as the better grade western magnetites of this class, that is about 55 per cent., and from this down. Phosphorus is usually below the Bessemer limit, adding much to the availability of the ores. Sulphur is usually too high to allow the ore to be used without roasting, seldom running less than .05 per cent., though by hand cobbing the sulphur content may be kept down somewhere near this limit. Concentration of certain of the leaner grade ores is likely to be commercially feasible in the future, though this is yet a moot question, especially with reference to the satisfactory elimination of sulphur. In a few places titanium is present.

Hematite has been mined at Wallbridge, Dalhousie and McNab in Eastern Ontario in similar geological relationships. According to Willmott,[6] there is reason for believing that they are oxidized portions of iron pyrites bodies lying below.

A deposit of magnetite not far from Bathurst, New Brunswick, seems from its available description[7] to belong to this class of pegmatite ores, but I do not have sufficient information to discuss it.

(3) Lake Superior Sedimentary Type.—Ores brought to the surface by igneous rocks and contributed either directly by hot magmatic waters to the ocean or later brought by surface waters under weathering to the ocean or other body of water, or by both; from the ocean deposited as a chemical sediment in ordinary succession of sedimentary rocks; and, still later, under conditions of weathering, local enrichment to ore by percolating surface waters. To this class belong most of the producing iron ores of the Lake Superior region, those of the Michipicoten district of Canada, and most of the non-producing banded iron formation belts of Ontario and Eastern Canada. The Lake Superior ores constitute the world's largest reserve of high grade hematite, more or less hydrated, much of it of Bessemer grade, and little of it high either in phosphorus or sulphur.

The ores of this class differ in origin from those of the preceding classes in that the iron, instead of being directly deposited near igneous rocks as ore, is distributed by the aqueous sedimentation and deposited with a large amount of interlayered silica in banded "iron formation," containing about 25 per cent. of iron, too poor to be used directly as ore, and requiring that the silica be locally taken out before they are of value. This ore may or may not show close areal association with the parent igneous rocks. It is obvious that gradation phases are to be expected between groups (2) and (3), and that many ore deposits can with difficulty be assigned definitely to one or to the other.

It has long been known that the Lake Superior ores were concentrates in certain sedimentary iron formations. It was believed that these sedimentary iron formations were derived from the weathering of basic shores containing much basic igneous rock usually called "greenstone." As a result of further study it has been found necessary to conclude that the iron formations have not only been derived from greenstone by weathering, but have actually been contributed by greenstone magmas directly to the water in magmatic solution and that there are all intermediate stages between the two processes. It begins also to appear that the iron, copper, nickel and silver ores of the Lake Superior and Lake Huron districts are related in a great metallographic province in which the characteristics and distribution of the different ores are initially controlled by igneous rocks.

This conclusion has an essential bearing on exploration, for if the iron is specifically related to certain greenstones, just as the Sudbury ores are to the norite, then it follows that its distribution may be somewhat freakish, as it is in any ores related to igneous activity, as for instance, the gold ores of the west, and that it cannot by concluded from similarity in succession or structure that iron ores should necessarily be found in a distant district, though the redistribution as sedimentary rocks which the iron ores alone have undergone has greatly increased their area and the chances of finding them.

As first deposited the iron formation consisted essentially of chemically precipitated iron carbonate or ferrous silicate (greenalite) with some ferric oxide, all minutely interlayed with chert. When these were exposed to weathering, the ferrous compounds, the siderite and greenalite, oxidized to hematite and limonite, essentially in situ, although some of it was simultaneously carried and redepoisted. The result was ferruginous chert called taconite or jasper, averaging less than 30 per cent. of iron. The concentration of the iron to 50 per cent. and over has been accomplished principally by the leaching of silica bands from the ferruginous chert and jasper. Infiltration of iron has been on a smaller and more variable scale. The leaching of the silica develops pore space, and allows the iron layers to slump, thereby enriching the formation sufficiently to constitute an ore.

It has been found, further, that during this leaching of silica the character of the iron bands has not essentially changed and therefore that the nature of the ore deposits is determined largely by the character of the ferruginous chert. The phosphorus is in the iron bands, rather than in the chert, and therefore the leaching of the chert tends to raise the percentage of phosphorus in the ore, but there has been also later introduction of phosphorus, making the phosphorus content of the ore considerably higher than that of the parent rock.

For flat-lying formation such as the Mesabi from 4 to 8 per cent. of the surface of the formation and less than 2 per cent. of the volume of the part of the formation lying vertically below this exposed surface have been altered to ore. For steep dipping formations like the Gogebic, about the same percentage of the volume has been altered to a depth of 2,000 feet.

There are a number of other facts of both scientific and commercial interest, especially relating to the quantitative determination of the various factors which have entered into the development of the present known deposits, which will be published by the U. S. Geological Survey, in a general monograph, by C. R. Van Hise and C. K. Leith and others.

I have discussed the Lake Superior ores only so far as necessary to bring out certain essential features of this class of ores in Canada and their bearing upon availability. There are many iron formation belts of this class, but they have been found to have undergone local enrichments to important ore deposits only in the Michipicoten district, and to some extent in the Animikie district.

In the Michipicoten district the ores are principally non-Bessemer and in portions of the deposits high in sulphur. Their occurrence beneath the peculiar Boyer Lake basin with walls of chert, tuff and carbonate, is well described by Coleman and Willmott.[8]

In the Animikie district the iron formation is an eastward continuation of the Mesabi iron formation, but it is less than 200 feet thick, as compared with 700 to 1,000 feet in the Mesabi, and has undergone enrichment only in thin layers interbedded with cherts and along a few fault planes. The thickness of the ore beds that may be mined will depend on how low a grade can be used and the success of hand sorting in keeping the ore up to this grade. Under any conditions much rock must be handled. On the other hand, the ores have great horizontal extent, are near the surface, are red hematite, low in phosphorus, with low sulphur, and practically on the shore of Lake Superior, justifying the hope that they may be used.

Two important questions remain to be solved in connection with the lean iron formation of the Lake Superior type so widely distributed in Ontario and elsewhere in Canada: (1st) Is their apparent lack of second concentration a real one? and (2nd) if so, what has caused it? On the assumption that the apparent lack of concentration is a real one, Van Hise has suggested that perhaps a part of the enriched portions has been removed by deep glacial erosion. Another alternative is that the structural conditions have not favored abundant flow of surface waters necessary for the leaching of the silica. A third possibility here most favored is that the original texture of the iron formations or proportions of the original constituents have been somewhat different from those of the Lake Superior region, and that they have not allowed access to the waters necessary to leach the silica. The formations are principally Keewatin and in general are more dense, crystalline and magnetic than the Huronian iron formations of the Lake Superior region. Some of these differences are doubtless due to secondary alterations, but it is not easy to account for all of the differences in this way. It is a significant fact, noted by Willmott,[9] that only 7 per cent. of the ore in the Lake Superior region have come from the Keewatin series, and that the Upper Huronian series, carrying 71 per cent. of the total, is not widely represented in Canada.

All these explanations and posibly others may apply. On the other hand, much more exploration is necessary to show that there really has not been concentration of large ore deposits in the known Canadian iron formations. The fact is again cited, that, in the producing Lake Superior districts, the proportion of ore, even under most favorable conditions, constitutes less than 8 per cent. of the surface of the iron formation and usually much less, and in volume it constitutes less than 2 per cent. Only rarely have the ores been discovered at the surface. Underground exploration through drift and rock has been necessary. In but few localities in Canada has there been adequate search for these localized concentrations within the iron formations. This fact is sometimes lost sight of because of marked tendency to use the term "iron ore" for the banded, unconcentrated "iron formation," and to speak of such formation as "lean, banded ore." In the Lake Superior region "iron formations" and "iron ores" are discriminated. It is not impossible that mechanical concentration of the iron formation may result in the production of ore, but it is unnecessary to argue the commercial advantage of finding some part of the iron formation in which nature herself has done the concentrating.

(4) Clinton Sedimentary Type.—Sedimentary ores deposited in oceans from weathering of the land areas in which the iron is either disseminated in igneous rocks or has undergone some of the concentrations outlined in (1)((2) and (3). To this class belong the "flax seed" ores of the Clinton and other beds of the Appalachians and Wisconsin, the ores of the Torbrook and Nictaux areas of Nova Scotia, and those of Bell Island in Newfoundland. They have now been discovered in Missouri.[10] They are also believed to differ in origin essentially from those of the preceding classes in that they are immediately derived by weathering processes, that they were deposited in the ocean as iron oxide rather than as ferrous salts, and that they have undergone no further concentration, being mined essentially in the condition in which they were deposited. There has long been some doubt as to whether or not these ores might not represent two concentrations, but work in the Southeastern United States by Eckel, Burchard and others,[11] for the U. S. Geological Survey, and our own observations in Wisconsin, seem to show one concentration.

On Bell Island the ores are beds dipping about 9 degrees to the northwest, in two main seams. The lower or Dominion seam averages about 10 feet in thickness, though variable, and extends across the island for about 3 miles along the strike and down the dip for perhaps half a mile, covering an area of 818 acres, although not productive for this entire area. The upper seam occupies an area about 1 by 1-3 mile (240 acres), averaging 7 feet in thickness and is not all productive. The mining has been largely open pit, but is becoming more largely underground as the ore is followed down the dip. They are now being followed under the ocean by

drifting. Much of the upper bed averages about 52 per cent. in iron, and the lower bed about 50 per cent. Recent shipments are reported to be under 50 per cent. Phosphorus averages 1 per cent. The ores are adapted to basic Bessemer or open hearth treatment, and for the former receive a bonus for high phosphorus from some European consumers.

In the Torbrook and Nictaux areas the ores are of similar kind, but the beds differ from those of Belle Isle in being thinner and inclined, requiring deep mining and handling of waste rocks.

Ores of this kind occupy a definite stratigraphic position, are easily explored for, and so far as their future in Canada is concerned, they have already been pretty well discounted.

(5) Carbonate Ores, derived from weather of rocks, transporated and deposited with organic reducing material in bogs; now found in thin beds usually associated with coal seams or carbonaceous shales. These have been extensively mined in the coal bearing and adjacent areas of the Eastern United States, but not in Canada. Their present production in the United States is almost nil. Where exposed to weathering they alter to limonite or brown ores, considered under the following heading. Iron carbonates constitute minor phases of class (3).

(6) Brown or Hydrated Ores, developed either from the weathering of iron carbonates mentioned in the preceding heading, or of limestones containing carbonate or other iron minerals, or by replacement of limestones or by deposition in glacial drift, or by bog deposition, or by some combination of them. The few limonites in class (3) are not here included. Being often residual products of weathering, they are characteristically mixed with other residual products of weathering, particularly clay. To use these ores it is necessary to wash out the other residual products, a process which nature neglected to attend to. The ores are characteristically hydrous and high in phosphorus, but when washed are found highly suitable for open hearth furnace practice.

The bog ores of Quebec presumably belong to this class.

Related to classes (5) and (6) are the Londonderry ores of Nova Scotia, consisting of carbonates of iron, calcium and magnesium, showing more or less alteration to limonite in irregular vein-like masses, in slate and quartzite. These ores are low grade, fairly high in phosphorus, manganese and silica, and are extremely irregular in their shape and distribution. Their origin is in doubt.

(7) Magnetic Sands.—Magnetic sands are developed from the erosion of classes (1), (2) and (3). As exposed along the lower St. Lawrence river they seem to be principally from classes (1) and (2), and are therefore high in titanium. They form beds from ½ inch to 2 feet in thickness, with wide extent. Their availability is still in doubt.

Commercial Importance of the Several Classes of Ores.—The proportions of the several classes of ores mined in the United States, Canada, and Newfoundland for 1906, appear in the subjoined table. Where the origin of the deposits is in doubt, the classification of their production is in doubt but the production from such types is too small to introduce any essential error into the figures given.

Production of Iron Ores in 1906.

	U.S.	Canada and Newfoundland.
Class 1. Magmatic .. segregation (magnetite)	.00	.0
Class 2. Pegmatite type (magnetite)	5.2	
Class 3. Lake Superior sedimentary type (hematite)	80.	12.29
Class 4. Clinton sedimentary type (hematite)	8.	78.34
Class 5. Carbonate type	1.	
Class 6. Brown ore type (limonite)	5.8	8.51

The dominance of class (3) (Lake Superior ores) in the United States production shows how desirable it is to have the ores go through nature's concentrating mill. These are the only ores which have undergone second local enrichments. That the less desirable grades of ore should compete at all with the Lake Superior grades is due largely to lower freights between ores and furnaces, between fuel and fluxing materials and furnaces, and between furnaces and consuming centres. Iron ores differ from most other metallic ores in that their great bulk, as compared with their value, requires cheap transportation, which operates in develop certain low grade deposits well situated in this regard at the expense of better grade ores.

Turning to the Canadian production, it appears from the table that the proportions of different classes of ores mined are quite different from those of the United States, and that a far larger proportion of Canadian ores is being drawn from less desirable classes. The class which produces 86 per cent. of the United States production produces only 12.29 per cent. of the Canadian production.

It appears, therefore, that in order to compete with the United States on equal terms so far as grades of ore are concerned, Canadian ores of the Lake Superior type must be more largely developed. The proportions and amounts of ores of the Lake Superior type now mined in Canada are not far different from those of the United States fifty years ago, before the advent of high grade Lake Superior ores had revolutionized the industry. It is not meant to imply that Canada is fifty years behind the times in this regard, but rather to call attention to its latent possibilities for the future and probable direction of development. It does not follow that the production of ores other than of the Lake Superior class may not also increase, because of low freights or artificial aids in the way of tariff or for other reasons.

Similar conclusions seem to follow from a consideration of ore reserves. I fully realize the uncertain nature of estimates of undeveloped deposits and the wide variety of figures that may be gotten by conscientious observers with different points of view or different methods, but certain essential features of our knowledge concerning reserves are fairly well established and a brief summary of them will help to bring the Canadian iron ore situation somewhat more definitely before us.

The titaniferous ores of class (1) not being mined, there is no point in attempting to warrant estimates.

The British Columbia magnetites of class (2) have been subject to a wide range of estimates depending upon how low a grade of ore is included, upon the

depth arbitrarily assigned, and upon the extent to which isolated portions of deposits are assumed to be continuous. Using only the extents and depths known, the tonnage of ore of commercial grade may be measured in a few tens of millions.

The difficulty of estimating the Atikokan and Hutton ore of class (2) is due to their mixture of greenstone, making it impossible to predict in advance of exploration of extent of the deposits. In both districts the explorations show at least several millions of tons.

For the Lake Superior ores of type (3) in the Michipicoten district, Coleman and Willmott have estimated a reserve of possibly two millions of tons. Some of this reserve is of doubtful value because of high content of sulphur. In the Animikie district the tonnage is problematic because of conditions described for that district, but at best the ores to be recovered is not in large amount. The reports of hundreds of millions of tons of the Lake Superior type is various parts of Canada so frequently seen in print are without foundation except as they cover commercially non-available lean iron formation rather than ores. Even under the best conditions but a small fraction of the iron of these formations is likely to be in ore of commercial grade.

The Grenville ores of lower Ontario show wide variations of estimates, depending upon the factors chosen. The known dimensions of commercial grades indicate not more than a very few millions of tons.

The similar beds of Nova Scotia are so thin that only a part of them can be counted as commercially available. A commercial estimate has been four million tons to level of 700 feet on the principal group of properties.

It appears in general, then, that the poportion of reserve of Canadian ores of the Lake Superior type to the total reserve is probably not greater than the proportion of their annual production to total annual production. It is not held for a moment that the tonnage of some of these deposits to be ultimately developed may not be considerably larger than here indicated, but whether they be increased or decreased, it will be because of introducing factors of depth or grade partly common to all of them. This is not likely to change their proportion sufficiently to obscure the fact that the most desirable ores of the Lake Superior type of class (3) are not yet developed in large enough tonnage to insure the future competition of Canadian iron ores with those of the United States on an equal basis. In competition with the great reserves of high grade ores of the Lake Superior region the principal Canadian reserves thus far developed suffer handicaps in grade and in content of deleterious constituents. These handicaps are and will be overcome to a certain extent by bounties or locally by favorable conditions of transportation, but that they exist is shown by the extremely vigorous search for iron ore of the Lake Superior type by Canadian mining interests, by the importation of Lake Superior ore to the amount of 4-5 of the ore used in Ontario, and by the recent increase in proportion of ore imported to home production, due to Canadian demand for finished products having gone ahead of the production from Canadian ores.

That ores of the Lake Superior type are in larger quantities in Canada than are now known seems likely, in view of the position of the Lake Superior region as a mere southern fringe of the great Canadian area of the pre-Cambrian rocks. Their discovery will require clearer search than has been previously made in any but isolated localities, for it is not only necessary to find the iron formation, but to find the small fraction of this formation which happens to have been concentrated. The vast area, the difficulties of travel, and the drift covering, requiring drilling, all combine to make the task a difficult one and partly explain why the search is not farther advanced. On the other hand, exploration may never develop abundant ores of the Lake Superior type for geological reasons discussed under class 3.

BOOK REVIEWS.

Rocks and Rock Minerals.—A Manual of the Elements of Petrology Without the Use of the Microscope By Louis V. Pirsson, Professor of Physical Geology in the Sheffield School of Yale University. 12 mo., V + 414 pages, 74 figures, 36 full-page half-tone plates. Cloth, $2.50 net (10/6 net). John Wiley & Sons, New York, 1908.

Not all mining men have an intimate knowledge of petrology, or the science of rocks. Even those who have had the advantage of a college course find that only a small residue of what they learned adheres to them.

Most text-books on the subject are cast into forms that repel the lay reader. Hence it is not easy for the beginner to acquire the rudiments of the science.

"Rocks and Rock Minerals" is an attempt to present the outlines of petrology in such a way as to give an intelligent idea of the subject to readers quite unacquainted with the microscopic standpoint.

Rocks and rock minerals are dealt with entirely from a megascopic, or practical outdoors, point of view.

The book before us attains the desired object of giving the reader a knowledge of rocks and rock minerals without recourse to the microscope. It is a very fair introduction to the study of geology generally. Part III, in which igneous, stratified, and metamorphic rocks are described, is an excellent treatise in itself. Simplicity is the keynote of the book.

A Guide to Technical Writing.—By T. A. Rickard, 127 pages. Price, $1. Mining and Scientific Press, San Francisco, 1908.

"Rules are useful, but the understanding of the reason on which a rule is based is better. No man can apply a rule intelligently until he understands when to disregard it." Thus writes Mr. Rickard in a prefatory note to this invaluable little volume.

Literary elegance is neither expected nor necessary in a mining engineer's report—and it is rarely discoverable in these documents.

As a record of facts and scientific deductions, engineers' reports and technical press articles are usually clear. But, not infrequently, this species of literature is turgid beyond description. Not only is it turgid, but it is abominably inaccurate and hazy.

One section of Mr. Rickard's book is entitled "Examples of Journalese." Here, clearly and briefly, the author gives instances of some of the most common inaccuracies and errors current in technical literature. We shall quote a few of these.

Lodes are often described to as being "permanent." "Persistent" is meant.

"Extensive" and "inaugurate," because of their mouth-filling qualities, are commonly chosen to replace the unassuming monosyllables "large" or "big" and "start."

"Installation, inaugurate, and prosecute are words that are the stock-in-trade of the boosters of wildcast."

Similarly the author. scores the unnecessary use of quotations from foreign languages. "The use of Greek or Latin, French or German, where Englsh suffices is a mark not of the literate, but of the pseudo-literate man."

That description and useful phrase "carries values" is condemned incontinently. Ores, or veins, do not carry "values;" they carry metals.

The chapter "Hints in Grammar" contains a most lucid explanation of the proper uses of "shall" and "will." Indeed, we cannot recall having read anything so clearly definitive. Particularly useful are the directions as to the correct use of singular verbs with such plural nouns as "500 tons of ore." "The idea is of a quantity of ore as a whole, all of which is treated in a continuous operation."

Among other minor matters the principles of punctuation, that bug-bear of the young writer, are set forth. The functions of the comma, colon, semi-colon, and the period are explained simply and well.

Questions of usage and of taste are not omitted. In this field Mr. Rickard may be followed almost implicitly.

Six maxims are presented as parting advice to the reader. They will bear repetition:

1. Have something to say; then say it.
2. When uncertain as to your grammar or phrasing, re-write the sentence or paragraph.
3. But do not tinker at a doubtful sentence; re-construct it thoroughly.
4. Avoid the use of words the meaning of which is doubtful to you.
5. Make your meaning clear; then consider style.
6. Remember the reader.

EXCHANGES.

The Mining Journal, June 27th, 1908.—Our London contemporary, after due consideration of the Coal Mines Eight Hours Bill, arrives at the conclusion that "the inevitable effect of shortening the hours of work, if the present rate of production is not reduced, must be to accelerate the rate of winding and all other operations underground." In this respect, then, the Eight Hours Bill, if it becomes law, will not improve the Miners' Act. Indeed, it will have a tendency in the opposite direction.

The wild generalizations "of the advocates of the Bill are easily refuted. It is contended by labor members that the death rate among miners is appalling. Statistics prove that as a class colliers are healthier and longer-lived than the average occupied male.

Mr. Walsh, a labor member, threatened that if the Eight Hours Bill were not passed, "trades union methods," which being interpreted means a general strike, would be resorted to.

This is the keynote of the situation. The Journal recognizes the moral certainty of enhanced prices of fuel to consumers, and alludes also to the highly probable increase in wages.

The Mining and Metallurgical Journal (Denver), July 3rd., 1908.—A strong editorial in this number outlines the education that should be acquired by the mining engineer. "The way of the engineering student is hard. A long school and college period is unavoidable; a hard course is his lot in college; his training cannot be confined to books and laboratories, for he must learn many things—such as etiquette and dealings with men—not taught in any schools, but in the walks of life."

Our contemporary predicts that the requirements of modern technical education will lengthen college courses to five and even six years.

PERSONAL AND GENERAL.

Mr. Alex. Gray, of Montreal, passed through Toronto on the 21st July after spending some time in Cobalt.

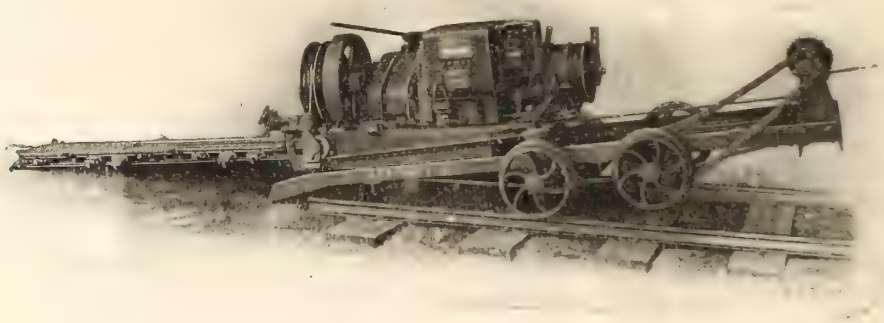
Dr. T. L. Walker, of Toronto University, is in the Lake of the Wods district searching for rare minerals.

Mr. Frank Loring recently examined and reported upon a deposit of gold-bearing mispickel in the Sudbury region.

Mr. W. F. Jennison, of Sydney, C. B., has been instructed by the Federal Department of Mines to prepare a monograph on the gypsum deposits of the maritime provinces.

Dr. Ells of the Geological Survey has been granted leave of absence on salary to go to Glasgow where he will witness experiments on a shipment of New Brunswick bituminous shale.

Mr. George J. Ross has resigned his position with the Acadia Coal Company of Stellarton, N. S., to become manager and resident engineer of the Lake Copper Mining Company at Copper Lake, N. S.



Mr. Frank J. Nicolas, late editor of the publications of the Geological Survey of Canada, has opened an indexing, cataloging and compiling bureau in Ottawa. Mr. Nicolas' work in compiling the general index for the Survey is evidence of his exceptional aptitude for this work.

INDUSTRIAL SECTION.

THE JEFFREY SHORTWALL COAL CUTTER.

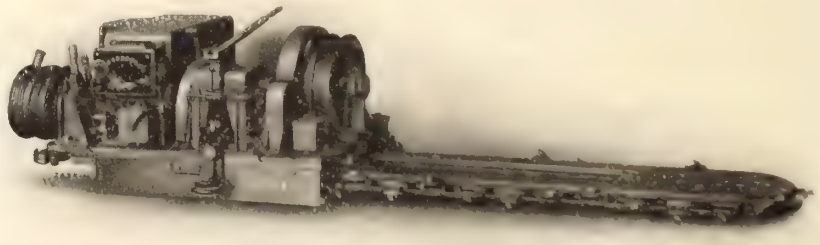
For Room and Pillar Work.

The economy and speed with which coal is mined by longwall machines has given rise to a very large demand for an efficient machine operating on the longwall plan, for room and pillar work. Special interest therefore attaches to an announcement that the Jeffrey Manufacturing Company has added to its line of electric coal cutters, a new room and pillar machine, known as the Jeffrey Shortwall Coal Cutter, 26-B., illustrations of which are here shown.

View of Jeffrey Shortwall Coal Cutter being loaded onto truck by its own power.

The difference betwen this and the well-known breast machines built by that company, is largely in the method of cutting. The new type cuts across the face of the coal, starting at one side of the room and not stopping until it finishes the cut at the other side.

A ½-inch steel feed cable wound upon a power driven drum at the front end of the machine pulls it across the face of the coal at a speed dependent upon, and suited to, the hardness of the cutting and the nature of the coal or clay in which the cutting is done. This drum when desired can be disengaged by means of a suitable clutch, so that the machine in finishing its cut at the left hand rib may be angled for the purpose of maintaining a uniform width of room. Another cable, having no connection whatever with the power, is arranged to act as a guide to hold the machine to its work at the proper angle for its greatest cutting efficiency.



Suitable sheave whels are provided at convenient points on the machine to guide the feed cable so that it can be led off in any direction, thereby enabling the machine to be loaded, unloaded, moved about and pulled out from under the coal by its own power,—a very desirable feature, and one which very strongly appeals to the machine runners.

The gearing is arranged so that the feed drum may be operated at a sufficiently high speed to move the machine quickly about the working place.

To take care of the heaviest service, an exceptionally powerful compound wound motor is provided.

The operation of the machine may be briefly described as follows: It is brought into the room on a truck moved by its own power or hauled by a mule, depending on whether or not a self-propelling truck is used.

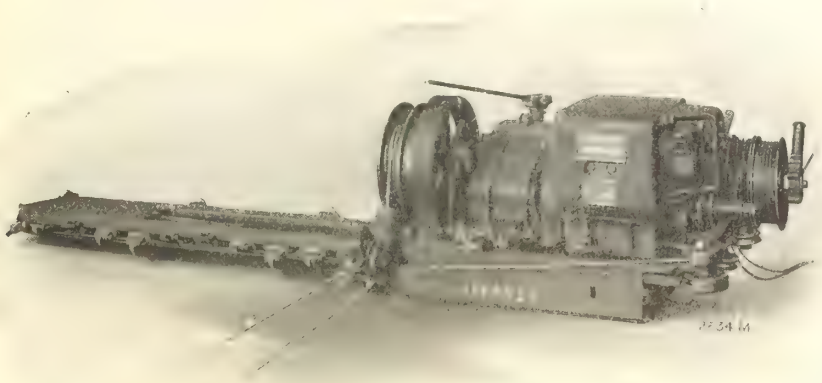
A pipe jack is placed at the face of the coal at the right hand rib and the feed cable attached. The motor is then started and the machine moved to the face of the coal. A simple guiding device, consisting of a piece of tee rail and one jack, is then set up on the left-hand side of the machine and the sumping cut started, the feed cable pulling the cutting frame in under the coal and the guiding device serving to hold the machine in line.

View of Jeffrey Shortwall Coal Cutter from control side.

When the sumping cut is completed, a steel anchor hook is secured by a wedge in the left hand rib near the face, to which are hooked one end of both the guide and the feed cables which lead across the face of

the coal. The cable is then attached to a jack set up at the right hand rib in line with the rear drums, and the machine started across the room. In operation, the feed cable pulls the machine across the coal face, and the guide cable keeps it at the proper angle to the face of the coal.

A special flexible brand of wire with elliptic stranding is used for the feed and guide cables, eliminating any tendency to kink or curl up when the tension is released, and materially increasing the wearing surfaces of the cable. The elasticity of the cables equalizes the shocks and jars on the machine and gives the motor an even, steady load.



When the machine reaches the left-hand rib, the pipe jack is moved to a position near the truck, the feed cable attached, the machine pulled out from under the coal and over to the truck where it is loaded by its own power and is ready to move to the next working place.

Among the advantages claimed by the Jeffrey Manufacturing Company for this, over any other make of side cutting machine, are:

1st. Its construction is simpler and stronger throughout, and the power of its motor equipment greater, qualifying it to perform longer and harder service and greatly reducing the danger of breakdown and the cost of up-keep.

2nd. It cuts faster, and less time is consumed preliminary to starting up and in removing the machine after the cut is finished.

3rd. It occupies less space and permits setting the props nearer to the face of the coal.

Jeffrey Shortwall Coal Cutter in position for cutting along face of coal. Note arrangement of feed and guide cables.

4th. It consumes substantially less power per cubic inch of coal cut.

5th. It is handled by its own power more rapidly and with less exertion on the part of the machine runners.

In addition to the 26-B. machine illustrated, the Jeffrey Manufacturing Company also builds a side cutter for thin vein coal, the construction and operation of which is essentially the same, no advantageous features being sacrificed to obtain the reduced height.

The Jeffrey Shortwall Room and Pillar Machine cutting across face of coal from right to left.

Both machines cut directly on the floor of the seam.

The motors furnished with these machines are of the most modern and improved types. The frames are made of cast steel with laminated pole pieces. The armatures are drum wound with form wound coils. The field coils are series wound impregnated with insulat-

Jeffrey Shortwall Coal Cutter beginning first or sumping cut at right hand rib.

ing compound and enclosed in oil and moisture proof covers. The commutator bars are of the best quality of hard drawn copper, and are insulated with mica of the proper hardness to insure even wear and long life.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay.

The Dominion Coal Company's output for the first half of July is about 175,000 tons, which considering that the period includes Dominion Day and the "glorious twelfth," is very good indeed. The outputs are maintaining a steady average of over 14,000 tons a day, and have on several occasions approached the 16,000 mark.

At No. 6 Colliery the work on the new haulage engine is well advanced. This engine is intended to meet the haulage requirements of No. 6 for a good many years. It is a powerful engine, cylinders 26 inches by 48 inches, set on a concrete foundation containing 300 cubic feet of material.

The Walker fan is erected. This fan will have an air capacity of 300,000 cubic feet per minute, and will be more than ample for No. 6 requirements. It is in keeping with the generally heavy and durable class of construction that has been carried on at No. 6 Colliery.

At No. 12 things are moving. The railway will be through and in operation at the end of August. The concrete pedestals for the bankhead are well under way, as is also the construction work on the permanent reservoir. The machine shop, wash-house, warehouse and several other buildings are near completion. The lamphouse is finished and equipped with 120 Ackroyd & Best safety lamps, which will be used in the mine after the 1st of August. The deeps are sunk about 1,350 feet.

At No. 14 the slope sinking is proceeding but is not being pushed. The dip is somewhat steep at the mouth of the slopes, but it is expected to flatten out rapidly as the sinking proceeds. The temporary plant is in course of erection.

The Department of Marine & Fisheries are making improvements in the navigation aids along the Cape Breton coast. They have just installed an acetylene buoy, with whistle and occulting light, in the fairway of Sydney Harbor, and it is understood they will replace the present Low Point Light, which has been in service seventy years, by a modern light, which with its buildings will cost about $16,000. A new fog horn is also being installed at Cape North. It is being built on a ledge of the cape and will have a sheer cliff, over 1,000 feet high behind it, so that the sound should be well projected to sea. During the summer months the waters between Montreal and Sydney are traversed by an endless procession of coal boats, going and coming, and as there is a good deal of fog along the route every aid to navigation is welcomed.

ONTARIO.

Cobalt.

At a meeting of the local branch of the Canadian Mining Institute held at Cobalt on July 17th, a very interesting paper on the origin of the silver in the Montreal River district was read by Dr. A. E. Barlow. Dr. Barlow stated that while he did not make the claim that the development of the James Township area would prove the existence of another Cobalt, yet he believed that the north country would show up a second and possibly a third Cobalt. Dr. Barlow was enthusiastic regarding the future of this new territory and his paper was greatly encouraging to the prospectors who are developing this district. An interesting discussion on the Mines Act was precipitated by a paper read by J. Lorne McDougall, Jr., on the application of the Mines Act. It was proposed that a meeting of the Cobalt branch of the Institute be called for the express purpose of discussing this very important question.

Temiskaming & Hudson's Bay Mine.—On July 14th, the T. & H. B. Mining Company declared a dividend of $6 per share, making a total of $107 per share distributed to the shareholders of this company to date on a par value of $1. This is the eleventh dividend paid by this company and the second paid this year.

Crown Reserve Mining Company.—The foundations for the power plant at this mine has been completed and the boiler and machinery is being installed. The working shaft, which is sunk on the vein, is down 160 feet. A station will be cut at this level and a drift run to the big vein.

The Cobalt Silver Queen Mining Company.—The fire which destroyed the power house at this mine on the morning of July 12th, will not materially affect the operation of the mine. The new 12-drill compressor was, with the exception of one cylinder head and the bearings practically uninjured, the boilers which are bricked in were not damaged. The principal loss will be the building, the repairs to the stack and hoist and the replacing of the lighting plant. The superintendent, Mr. Robert A. Bryce, has the construction of the new power house well under way, and has arranged with the Cleveland Cobalt for air supply until the plant is repaired. A pipe line has been laid from the Cleveland Cobalt and three drills are running at the mine.

Montreal River District.

The diabase area extending south of Silver Lake, through Thompson and Boland Lakes to Hubert Lake, a distance of about seven miles, and the territory surrounding Silver Lake includes some of the most promising prospects in the Montreal River district. A large majority of the claims in this belt upon which any real prospecting has been done, have one or more discoveries of native silver. In the southeast portion of this area adjoining Silver Lake, the Downey claim T. R. 386 has an aplite vein six to eight inches wide which carries high values in native silver and compares favorably in value with the rich bearing veins in the Cobalt camp. This property is tied up in litigation and very little development work has been done. Twenty odd claims to the east of Silver Lake have native silver discoveries of more or less importance, and new discoveries are continually being made.

South of the lake on two claims belonging to Bernard Micmac, good discoveries have recently been made. Cornering on one of these claims and west of Silver Lake is T. R. 224, belonging to Sam Otisse, probably one of the most valuable claims in the Montreal River district. While no sinking and practically no trenching has been done, six important leads showing high values in native silver, have been located. As in the majority of the veins showing native silver in this section of the camp these veins are calcite or aplite, in most cases decomposed on the surface, in which the silver is found freed and lying in a black muck. All of these veins run east and west and average three to four inches in width. The latest discovery on this property made some weeks ago is a vein or dyke of gabbro thirty inches wide, on each side of which is a narrow vein of decomposed calcite one to two inches in width. In these small veins are found nuggets of very pure, white silver and the gabbro is heavily shot with leaf silver. This vein has been uncovered for seventy feet, and wherever opened up shows native silver. It is reported that this property has recently been sold to an English syndicate for a very large sum.

On the five claims belonging to the Clinton & Steindler Syndicate lying west of Silver Lake, a considerable amount of prospecting has been done with very encouraging results. On J. S. 174 a vein of aplite and galena, which assays 37½ per cent. lead and carries small silver values, is being developed. Four out of five of these claims have native silver showings in calcite, cobalt or aplite veins, and with further development, which is now being carried on, these properties should show up well and rank among the best properties in the district.

North of the Clinton & Steindler properties separated by several claims which have not been prospected are the Thompson and Boland properties which include the seven claims in the immediate vicinity of Thompson and Boland Lakes. All of these claims have good discoveries and nine veins have been located which show native silver. North of these claims between Boland Lake and Hubert Lake, the Fisher, Conley and Fraser properties are situated on all of which promising discoveries have been made. In the vicinity of Hubert Lake Otisse has native silver in three veins and several strong leads of smaltite and niccolite. The Doctor Hentchell, and the Currey properties near Hubert Lake, upon which a considerable work has been done, rank with the best properties in the district.

The chief drawback in the development of this section is the difficulty in obtaining funds for prospecting. There is every reason to believe that with proper attention this section will prove up some shipping mines.

ALBERTA.

Strathcona.

What will eventually be one of the largest coal mines in this district has just started sinking operations along side the Edmonton Yukon & Pacific Railway, which connects Edmonton and Strathcona.

The company operating on the property is the Twin City Coal Company with head offices in Toronto. A. Arthur Laurie of Toronto, is president of the company. It has been decided to put down a plant for handling 500 tons of coal per day. Coal cutting machines of the most modern type driven by compressed air, wil be introduced. The seam of coal to be mined is seven-foot cheek, lying about 120 feet below the surface.

District No. 18 of the United Mine Workers of America have decided to appeal to the Supreme Court of Alberta against the decision of Judge Stuart in dismissing the action for $12,000 damages entered by the U. M. W. of A. against the Strathcona Coal Company for a violation of their agreement made under the provisions of the Lemieux Act.

The appeal will be entered on the ground that section 62 of the Lemieux Act provides for the enforcement of an agreement made under that Act, and also that a miner's union has a right to make an agreement collectively and have therefore the right to sue collectively.

The decision to appeal this case was the result of a meeting of the officers of District No. 18 of the United Mine Workers of America, and the various solicitors of that organization held in Calgary recently.

Mr. Frank H. Sherman, President District No. 18, U. M. W. of A., when interviewed in Edmonton on Judge Stuart's decision, said: "We are surprised at the decision given by Judge Stuart. We believed in the Lemieux Act and were under the impression that Judge Stuart believed in it too. Under that Act, Judge Stuart has four times been chairman of conciliation boards in Alberta.

"Last fall he was chairman of a conciliation board held under the Lemieux Act at Lethbridge. He was on the bench then, and upheld on that as on the other occasions, agreements made under the Act he now finds against, as far as the Strathcona agreement was concerned.

"The judge states now that the men have no right to make an agreement collectively, but the union belives that the Strathcona agreement is the same as those made in the South and that the Lemieux Act is still good.

"The two important sections on which we depend are Nos. 24 and 62. The former says: 'If a settlement of the dispute is arrived at by the parties during the course of its reference to the board, a memorandum of the settlement shall be drawn up by the parties and shall, if the parties so agree, be binding as if made a recommendation by the board under section 63 of this Act, and a copy thereof together with a report of the proceedings shall be forwarded to the Minister.'

"That section provides for the two parties coming to an agreement without waiting for the board's recommendation

Section 62 governs the recommendation of the board. Here it is: 'Either party to a dispute which may be referred under this Act to the board, may agree in writing at any time, before or after the board has made its report and recommendation, to be bound by the recommendation of the board in the same manner as parties are bound upon an award made pursuant to a reference to arbitration on the order of a Court of Record; every agreement so to be found made by one party, shall be forwarded to the registrar, who shall communicate it to the other party, and if the other party agrees in like manner to be bound by the recommendation of the board, then the recommendation shall be made a rule of the said court on the application of either party, and shall be enforceable in like manner.'

"We believe in the Lemieux Act," repeated Mr. Sherman, "we know it is a power for good where it is a power at all. It makes for peace and good understanding between employers and employed, and we believe those two sections are good law in the Strathcona case and all over Alberta. Anyway we are appealing and will try to get the Act upheld."

BRITISH COLUMBIA.

Rossland.

During the week ending June 20th, 4,685 tons of ore were sent out from Rossland camp, included in this was a car of hand picked galena ore shipped from the Mayflower. This ore was selected with due care and will return the lessees in the neighborhood of $1,000 for the car. The men now working the Mayflower have another car of ore about ready to ship. The extraction of good ore still continues on the Blue Bird.

The shipments of ore from Rossland for the week ended July 2nd, were 5,405 tons; a little heavier than they have been running lately. The Centre Star shipped 3,550; Le Roi 1,470 and the Josie 385 tons.

Considerable interest is being taken in the anticipated visit of the Canadian Mining Institute and their guests and friends to this camp and the surrounding district in September. A meeting of the Western Branch of the C. M. I. was held here recently and arrangements were discussed for the entertainment of this distinguished party. A committee of prominent mining men was appointed to arrange a programme and there is no doubt but this party will enjoy the usual hospitality that is extended to visitors to this section of the country.

The gross value of the output of the Consolidated Mining & Smelting Company of Canada, of Rossland, also operating in Moyie, Phoenix and at Trail, for nine months of the current fiscal year, which ended June 30th, was $4,178,786, which is $100,000 more than for the entire fiscal year of 1907. It is needless to say that the Consolidated Company's report for the year will show a favorable season of operation.

Boundary.

Work is now being energetically prosecuted on four of the Dominion Copper Company's mining properties in this district, the Rawhide, Sunset and Idaho being operated. The large furnace at the Boundary Falls smelter has been put into operation. This machine has a capacity of 650 tons of ore per day and the two smaller ones, which will be blown in just as soon as conditions at the smelter warrant, have a combined capacity of 600 tons.

Mr. W. C. Thomas has returned to the Boundary from Salt Lake City to make a final arrangement of affairs here, as he has resigned as manager of the Dominion Copper Company to take charge on a Newhouse property in Utah,and will be succeeded by Mr. P. F. Roosa, formerly assistant manager. There being a good supply of coke on hand at the smelter, plenty of water, the ore bins full and the stopes in the mines filled with broken ore, conditions were very favorable for a prompt resumption of work at the Dominion Copper Company's properties. The Dominion Copper Company properties appear on the shipping list during the week ending July 2nd for the first time in a long while. The following were the ore shipments for that week:

	Tons.
Granby	20,522
Mother Lode (B. C. C.)	5,840
Oro Denoro	1,190
Rawhide (D. C. Co.)	11,500
Brooklyn (D. C. Co.)	104
Sunset (D. C. Co.)	450
Mountain Rose	45
Total	29,751

The weekly shipments from this district are beginning to exhibit some of their old time weightiness. The total tonnage sent out for the year is 599,768 tons.

Jay P. Graves, general manager of the Granby, paid his properties a visit about a week ago and expressed himself as very well pleased with the way things had been done around the workings. The improvements, which have cost over $500,000, were all in line with his approval and will mean a material reduction in the cost of production of ore and copper matte. The company is realizing a profit, but it is necessary under the circumstances to utilize every possible improvement and money-saving device in order to secure such a profit.

The British Columbia Copper Company has got down to hard work and are turning out about a car of blister copper per day from the convertors at the smelter. They expect to increase their output materially in the near future. The statement following, which gives the operations of the British Columbia Copper Company smelter during the fiscal year ended November 30th, 1907, will give one a reasonable idea of the work done:

	Pro.	Realized.
Refined copper (pounds)	8,643,133	$1,579,907
Silver (ounces)	101,114	67,274
Gold (ounces)	24,967	512,233
Total		$2,159,414

They received an average of 17.52 cents per pound for their copper.

The British Columbia Copper Company is receiving ore at its smelter regularly from the Napoleon and Lone Star mines, controlled by them and situate in the State of Washington, but they have not begun shipments from their holdings near Danville, Wash., so far.

Mining is quite active in the vicinity of Grand Forks and Nelson on the smaller properties. More work is being done in a development way this year than has been done for some years past. This is no doubt in view of the improved condition of the market for small but meritorious mining properties, which is quite noticeable here in the west.

On the C. P. R. Claim in Franklin camp recently an assay was obtained from rock in the bottom of a 20 foot shaft which gave returns of: $380 in gold, $15 in copper and some silver

A ledge has been located near Nelson carrying native and ruby silver. Ore found on the Mayflower and Hilltop, Sheep Creek district, carries 16 ounces gold, 64 ounces silver and 7 per cent. copper. The Sheep Creek country is presenting a very lively appearance this season and is slowly forging to the front.

GENERAL MINING NEWS.

PRINCE EDWARD ISLAND.

Charlottetown.—An appropriation of $35,000 has been made by the Dominion Government, most of which is to be spent in boring for coal in this province. The discovery of merchantable coal would be of immense benefit to the island.

ONTARIO.

Ottawa.—The following is the text of the lead bounty extension bill:

An Act respecting the payment of bounties on lead contained in lead-bearing ores mined in Canada.

Whereas under the provisions of an Act passed on the 24th day of October, 1903, being chapter 31 of the Acts of 1903, payment of a bounty on lead contained in lead-bearing ores mined in Canada, not to exceed five hundred thousand dollars in any fiscal year, was authorized to be paid until the thirtieth day of June, 1908; and whereas the total amount of bounty paid thereunder up to the thirty-first day of March, 1908, was six hundred and sixty-six thousand nine hundred and twenty-two dollars, and it is estimated that a further amount of forty-five thousand dollars will be payable on or before the thirtieth day of June, 1908, leaving unexpended about one million seven hundred and eighty-eight thousand and seventy-eight dollars of the total amount authorized to be paid under the provisions of the said chapter 31: Therefore His Majesty, by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows:

1. The Governor in Council may authorize the payment of a bounty of seventy-five cents per one hundred pounds of lead contained in lead-bearing ores mined in Canada, on and after the first day of July, 1908, such bounty to be paid to the producer or vendor of such ores: Provided that when it appears to the satisfaction of the Minister charged with the administration of this Act that the standard price of pig lead in London, England, exceeds fourteen pounds ten shillings sterling per ton of two thousand and forty pounds, such bounty shall be reduced by the amount of such excess.

The total amount of bounty payable under the provisions of chapter 31 of the Acts of 1903, and of this Act, shall not exceed two million five hundred thousand dollars.

2. Payment of the said bounty may be made from time to time to the extent of sixty per cent. upon smelter returns showing that the ore has been delivered for smelting at a smelter in Canada. The remaining forty per cent. may be paid at the close of the fiscal year, upon evidence that all such ore has been smelted in Canada.

3. If at any time it appears to the satisfaction of the Governor in Council that the charges for transportation and treatment of lead ores in Canada are excessive, or that there is any discrimination which prevents the smelting of such ores in Canada on fair and reasonable terms, the Governor in Council may authorize the payment of bounty, at such reduced rates as he deems just, on the lead contained in such ores mined in Canada and exported for treatment abroad.

4. If at any time it appears to the satisfaction of the Governor in Council that products of lead are manufactured in Canada direct from lead ores mined in Canada without the intervention of the smelting process, the Governor in Council may make such provision as he deems equitable to extend the benefits of this Act to the producers of such ores.

5. The bounties payable under the provisions of this Act shall cease and determine on the thirtieth day of June, one thousand, nine hundred and thirteen.

6. The Governor in Council may make regulations for carrying out the intention of this Act.

Sault Ste. Marie.—The Lepage Gold Mining Company, which is operating the Grace Mine at Michipicoten, held its annual meeting of stockholders at Minneapolis recently, when a new board of directors was elected. The members of the board are: President Dr. D. A. Stewart, Winona, Minn.; M. B. Webber, Winona, Minn.; L. S. Peek, Minneapolis; J. H. Foster, Minneapolis; A. B. Robbins, Elroy, Wis.; N. C. Eklund, Basa, Minn. Mr. Angus Gibson was reappointed general manager of the company, and Mr. Roy Earle will continue as superintendent at the mine. Ten stamps are to be added to the present mill.

Madoc.—The talc-grinding mill is now in operation. An output of from 10 to 12 tons of various grades of ground talc per day is expected. This is an important addition to Madoc's activities.

Cobalt.—The power plant of the Silver Queen was burned to the ground on Sunday morning, July 12. Repairs to the machinery are being rushed with all possible speed. Meanwhile a supply of compressed air is arranged for with the Cleveland-Cobalt Company. The damage is estimated at $5,000, fully covered by insurance.

BRITISH COLUMBIA.

Nelson.—Mr. John L. Retallack, who did excellent work in connection with securing an extension of the lead bounty, has succeeded in organizing a company to take over the Whitewater Deep property.

Rossland.—At the St. Eugene mine at Moyie, several discoveries have been made lately. An extension of the south ledge has been found and it is expected that the ore bodies of the mine will be largely increased thereby.

Nelson.—The Kootenay Development Company has taken a lease on the Silver King mine and Hall Mines smelter, and is erecting a pole line to electrify the property, and will unwater by that means levels to depth of 800 feet. This will mean the employment of over 100 men on the mine berore Christmas.

Phoenix.—A new and promising ore body has been struck at the Brooklyn mine of the Dominion Copper Company.

Nelson.—After years of litigation, the Last Chance mine, near Sandon, one of the Slocan's principal silver shippers, will be again operated.

Victoria.—Mr. J. T. Shadforth announces that capital for the erection of a steel plant has been secured. The blast furnaces will be situated near one of the Vancouver Island collieries. Beyond this, no definite announcement has been made.

MINING NEWS OF THE WORLD.

GREAT BRITAIN.

The wages of Northumberland coal miners have been reduced 2½ per cent.

Mr. John Cadman, D. Sc., has been appointed to the chair of Mining at Birmingham University.

The extension of Leeds University including the departments of mining and metallurgy, elaborately equipped, was opened by King Edward on July 7th. The cost was largely met by the Yorkshire coal owners.

The Welsh Navigation Steam Coal Company, who have been sinking in the Eby valley two years, have struck te celebrated No. 3 Rhondda seam of coal at a depth of 1110 feet, proving an area of 3,000 acres of coal.

FRANCE.

Mons. P. Barbier has discovered a new variety of mica at Mesvries, which cannot be classed in the muscovite group, but it is more like paragonite in composition, though it has not the same external characteristics. It is distinguished from muscovite by its percentage of lithia. The discoverer has given it the name of hallerite.

NORWAY.

The Hohenlohe-Werke Company, Oberschlesien, has obtained for one of their subordinate Norwegian companies a concession of extensive zinc claims in Hakedal and Nannestad near Christiania. The concession is for 82 years at the end of which the mines and plant revert to the State. The company will employ from 600 to 700 men.

RUSSIA.

The yield of asbestos in the Ural has steadily increased from 64,654 poods in 1893, to 571,194 poods in 1907. Owing to the increased prices other areas are being prospected. It is stated that recently large and rich deposits of this mineral have been found in the Altay mining district, a concession for the exploitation of which has been granted.

GREECE.

Large exports of magnesite from the Piraeus district to Britain, Germany and America have laterly been made. The Anglo-Greek Magnesite Company has undertaken the sale of the produce of the Greek Societe des Travaux Public et Communeaux, the latter being bound to deliver annually 42,000 tons, to effect which they will open up new deposits and increase their plant.

Two new companies have been floated for working iron ores in the Pireans district, where large deposits occur. It is reported that extensive quantities of rich iron ore also exist near Karditza Baotia, and a company is being organized to operate them.

AUSTRALASIA.

Production at the tin mines of Tasmania was on a much greater scale during the first three months of 1908 than for the corresponding period last year, the figures being 1,045 tons of black tin, as against 586. Some recently located ore bodies of the Mount Bischoff Company are opening up satisfactorily.

The Zinc Corporation at Broken Hill, New South Wales, has been more successful since adopting the Elmore process of concentration, by which 10,810 tons of tailings were treated during April. Costs have been so reduced that a profit can be realized even at present prices.

The output of gold in New Zealand during June amounted to 47,416 ounces, valued at £190,656, as compared with 26,702 ounces valued at £104,456 in June, 1907.

SOUTH AFRICA.

The Transvaal Government has decided to take over a worked or developed mine in conjunction with the Chamber of Mines and utilize it as a training school for skilled miners.

The Robinson Gold Mining Company of Johannesburg made another record in the reduction of working expenses for May last, bringing the costs down to 12s. 4½d. per ton.

The African Diamonds Corporation and the old Driekopjes Company have been merged and work has been resumed on the Driekopjes property.

UNITED STATES.

There are now twelve shipping mines in the Rawhide, Nev., camp and but one mill in operation, which is being enlarged to a capacity of 120 tons per day. The ore treated yields from $30 to $50 per ton. Several other mills will shortly be started.

The Nova Scotia Steel Corporation having nearly completed stripping at the Norman-Ohio iron property at Virginia on the Mesabi range, Mich., preparations are being made for the extensive mining of the tract.

The Beatson copper mine on Latondie Island, Alaska, isre ported to have $10,000,000 worth of copper in sight. The out put from the smelter at Tacoma to 1907 was [illegible] pounds copper and 9,000 of silver. Production is purposely restricted on account of high transportation and smelter charges.

At the Williamston colliery of the Susquehanna Coal Company, in the lower part of the anthracite coal fields of Pennsylvania, seven miners were killed and ten injured by an explosion of gas on July 15th. The mine was wrecked and set on fire.

COMPANY NOTES.

The Crow's Nest Pass Coal Company on July 16th distributed a stock bonus to its shareholders of 66 2-3 per cent. and later on declared a half yearly dividend of 3 per cent., payable August 1st, on the basis of the new stock. This is the same as 10 per cent. on the old stock.

In July the following dividends will have been paid by Cobalt companies:

Nipissing, 3 per cent. quarterly	$180,000
McKinley, 3 per cent. quarterly bonus 2	112,346
Kerr Lake, 2 quar., bonus 1	90,000
Crown Reserve, 4 p.m., ½ year	80,000
Temiskaming, 3 per cent., quar	[illegible]
Hudson Bay, 86	[illegible]
Buffalo, 3 per cent., quar	27,000
City of Cobalt, 3 interim and bonus 2 per cent	25,000
Total	[illegible]

COBALT ORE SHIPMENTS.

Following are the weekly shipments from Cobalt camp, and those from January 1st to date:

	Week end. July 11. Pounds.	Since Jan. 1. Pounds.
Cobalt Lake	95,228	341,683
La Rose	83,100	2,631,662
Kerr Lake	60,674	522,974
Nipissing	127,007	2,283,747
Nancy Helen	187,007	327,427
O'Brien	191,307	3,412,777
Peterson Lake	41,237	41,237
Silver Queen	180,000	814,510

The total shipments for the week were 965,560 pounds, or 483 tons. The total shipments from January 1st to date are 19,048,813 pounds, of 9,524 tons. The total shipments for the year 1907 were 28,081,010 pounds, or 14,040 tons, valued at $6,000,000. In 1904 the camp produced 158 tons, valued at $130,217; in 1905, 2,144 tons, valued at $1,473,196; in 1906, 5,129 tons, valued at $3,900,000.

Shipments of ore from the Cobalt camp for the week ended July 18 totalled 1,011,000 pounds., or 505 tons, a record output, divided among eight mines. Shipments from January 1st to date total 20,059,813 pounds, or 10,003 tons. Mines and shipments were:

	Week end. July 18. Pounds.	Since Jan. 1. Pounds.
Buffalo		696,390

Watts		306,180

*Concentrates.

The output of the Crow's Nest Pass collieries for the week ending July 10th was 22,261 tons, a daily average of 3,710 tons. Week ending July 13th, 1907, 24,015 tons; daily average,

4,002 tons; wek ending July 13, 1906, 18,108 tons; daily average, 3,018 tons.

The gold production of the Transvaal mines last June was officially placed at 574,973 fine ounces. This was a loss of 7,000 ounces from May, but an increase on last Saturday's estimates of 5,000. The value of the month's output was $12,200,000.

BRITISH COLUMBIA ORE SHIPMENTS.

Nelson, July 11.—The following were the ore shipments from the mines and the receipts at the smelters of the districts of Southeatsern British Columbia for the past week and year to date:

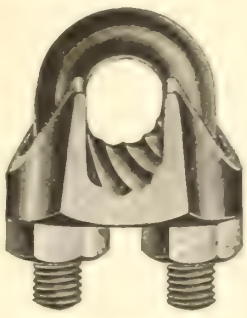
Amatite ROOFING

Amatite has one distinction which makes it stand out above all others. **It has a real mineral surface.**

It is [illegible] the freedom from painting or coating. [illegible] of weather.

This mineral surface is embedded in a layer of Pitch, **the greatest known waterproofing material.** Beneath this in turn are two layers of the best grade of felt—cemented together by more Pitch, making the whole a roofing that is **absolutely fireproof.**



No other ready roofing can compare with [illegible] proof, weather-proof, durable roof. That's what we say—**Don't buy your roofing until you have seen Amatite.**

Free Sample and Booklet

Send for Free Booklet and Sample to-day. It will pay you to get acquainted with Amatite. Address nearest office.

PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assayer. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals and extending northward from the great lakes and westward from the Ottawa river to the Manitoba boundary.

Iron inlarge bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The allied metal, cobalt, is also found in Ontario in unsurpassed quantities.

The output of iron, copper, nickel, silver and cobalt in 1906 was much beyond that of any previous year, and large developments in these industries are now going on.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output.

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

HON. FRANK COCHRANE,
Minister of Lands, Forests and Mines,
Toronto, Canada.

PROVINCE OF QUEBEC

The attention of Miners and Capitalists in the United States and Europe is invited to the

Mineral Territory Open for Investment in the Province of Quebec

Gold, Silver, Copper, Iron, Asbestos, Mica, Plumbago, Phosphate, Chromic Iron, Galena, Etc. **Ornamental and Structural Materials in abundant variety.** The Mining Law gives absolute security to title and has been specially framed for the encouragement of mining

All mines belong to the Government of the Province on all unsold lands and on all those sold since the 24th July, 1880, but gold and silver are always reserved whatever may be the date when the land was sold, unless it be otherwise mentioned in the patent.

The Government grants PROSPECTING LICENSES for lands on which the mines belong to it, giving the holders of such license the first right to purchase the mines. In the case of lands where the surface only is sold, the owner of the surface may be expropriated if he refuses an amicable settlement

The price of prospecting licenses is $5.00 per hundred acres on surveyed lands and per square mile on unsurveyed lands. If the surface has already been sold, the price is only $2.00. They are valid for three months and are renewable at the discretion of the Minister.

When mines are discovered, they can be bought or leased from the Government. The purchase price is as follows:—

On lands situate more than 20 miles from a railway in operation, $10.00 per acre, and on lands situate less than 20 miles from such a railway, $20.00 per acre:

Superficial products and building materials are sold $2 and $4 an acre according to the distance from rail road.

MINING CONCESSIONS are sold in entire lots in surveyed townships or in blocks of not less than 100 acres in unsurveyed territories.

Patents are obtained subject to the following conditions: The full price must be paid in cash; specimens must be produced and accompanied by an affidavit; a survey at the cost of the applicant must be made on unsurveyed lands; work must be bona fide begun within two years and $500.00 spent for each 100 acre concession.

MINING LICENSES, giving the right to work the mine and dispose of its products, are granted on payment of a fee of $10.00 and a rent of $1.00 per acre per annum. Such licenses are valid for one year and are renewable on payment of the fee and of the same rent. They may cover from 1 to 200 acres or one and the same person, and must be marked out on the ground by posts

The description or designation must, however, be made to the satisfaction of the Minister.

Persons working mines must send in yearly reports of their operations to the Government

The attention of the public is specially called to the new territory north of the height of land towards James Bay, which comprises an important mineral belt in which remarkable discoveries of minerals have already been made, and through which the new Transcontinental Railway will run.

The government has made special arrangements with MR. MILTON L. HERSEY, 171 St. James St Montreal, for the assay and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. Tariffs of assays can be obtained on application to him.

The Bureau of Mines, at Quebec, will give all the information asked for in connection with the mines of the province, and will supply maps, pamphlets, copies of the law, tariff of assays, etc., to all who apply for same.

Applications should be addressed to:

The Hon. Minister of Colonization, Mines and Fisheries
Parliament Buildings, Quebec.

Province of Nova Scotia

Leases for Mines of Gold, Silver Coal, Iron, Copper, Lead, Tin

AND

PRECIOUS STONES

Titles given Direct from the Crown, Royalties, and Rentals Moderate

Copies of the Mining Law and any information can be had on application to

The Hon. Christopher Chisholm

Commissioner Public Works and Mines, - - HALIFAX, NOVA SCOTIA

JUDICIAL SALE

of all Assets of the Copper Mining and Smelting Company of Ontario, Limited in Liquidation.

Sealed tenders will be received, addressed to His Honor F. W. Johnson, Local Master, Sault Ste. Marie, Ontario, and marked "Tenders in THE COPPER MINING AND SMELTING COMPANY of Ontario, Limited, Liquidation," up to twelve o'clock noon on the Fifteenth day of September, 1908, for the purchase of all the assets of the said Company now in the possession and control of the Liquidators, which assets consist of the valuable Mine and Mining Property situated in the Town of Bruce Mines in the District of Algoma and Province of Ontario, on the North shore of Lake Huron (where there is a good harbour and shipping facilities) with machinery, buildings, plant and full equipment situated on the premises, and wharfage, railway tracks and sidings.

Tenders will be received for the entire property or for any of the following parcels:

PARCEL 1

Mine, Mining Rights, Buildings, Machinery, Plant, Concentrating Mill, Railway Track and Sidings, Coal Dock, Skimpings, Slimes and Ore already won. There are two principal working shafts some 500 feet in depth, which have been in full operation until recently. The property consists of all the mineral rights in two grants or locations, embracing an area of some 20 square miles (with the exception of 116 acres already disposed of), also the surface rights of about 665 acres of said lands (of which 300 acres are within the limits of the Town of Bruce Mines).

Bruce Mines Station of the Canadian Pacific Railway, situated on the property, is 135 miles from Sudbury and 37 miles from Sault Ste. Marie. The Bruce Mines and Algoma Railway here crosses and runs down to the Lake, having a station and sidings convenient to the mines.

THE BUILDINGS, adapted to large operations, are in good condition, and consist of machine shop, fully equipped, blacksmith's shop, store houses, oil house and boiler houses, two power houses, mill offices, Manager's and Mill Superintendent's houses, boarding house, ice house, stable and dynamite magazine.

THE MACHINERY AND PLANT, which are in good running order, have an inventory valuation of $96,500.00. The concentrating mill, situated on the Lake front, has a capacity of 250 tons per day and pumping plant of 60,000 gallons per hour. Its construction and equipment cost $130,000.00. The Electric Light plant has a capacity of 500 lights. One and one half miles of Railway Track (with sidings) connect the mine proper with the Concentrating Mill and Coal Dock, where vessels drawing 16 feet can load and unload.

THE SKIMPINGS, estimated at 120,000 tons, are useful for fluxing purposes in nickel smelters, and for the manufacture of artificial stone. A separate tender for these skimpings will be considered. The ore already won and in the stopes is estimated at 9,000 tons. Considerable development work has also been done on the property exposing a large body of ore.

PARCEL 2

TOWN AND PARK LOTS, containing about 300 acres within the town limits, sub-divided into over 100 convenient building lots.

WATER LOTS, situated in front of the Concentrating Mill and adjoining the coal dock.

ISLANDS: "French," "McCoys," "Bruce," "Rat," "Mouse," having in all an estimated area of 75 acres, with some suitable lumber-mill sites.

PARCEL 3

RANGE LOTS, consisting of about 365 acres in the Township of Plummer Additional.

PARCEL 4

WHARF AND WAREHOUSES, conveniently situated adjoining the Government Dock, with 16 feet depth of water.

Tenders for separate lots and islands mentioned in parcels 2 and 3 will be considered.

The principal workings are being kept free of water and will be open for examination by intending purchasers. Full descriptions and particulars of the real estate and full details, inventories, etc., of the plant, machinery and other assets of the Company can be obtained upon application to the Liquidators T. Hayes Sheen, Jnr., at Bruce Mines, Ont., or R. C. Jennings, 18 Toronto Street, Toronto. A full inspection of all the property may be had at any time.

As to the real estate, it is understood that the foregoing description is only a general description and the areas given are only approximate and the purchaser is to satisfy himself as to the quantity of land and the title of the Company thereto and shall search the title at his own expense and the liquidators will not be required to furnish any abstract of title or to produce any title deeds other than those in their possession.

TERMS OF SALE: 10 per cent. cash; 40 per cent. within 30 days, and balance within 60 days with interest at 7 per cent., secured to the satisfaction of the Liquidators. The tenders must be accompanied by a marked cheque, payable to the Liquidators for 10 per cent. of the amount of tender, which will be returned if tender is not accepted.

The highest or any tender not necessarily accepted.

The other conditions of sale are the standing conditions of sale of the Court as far as applicable.

For further particulars and conditions of sale, application may be made to either of the above-named Liquidators or their Solicitors.

DATED at Sault Ste. Marie this Third day of July, A.D., 1908.

F. W. JOHNSON, Local Master.

HEARST, McKAY & DARLING, Sault Ste. Marie, Ont.
Solicitors for Liquidators.

BRITISH COLUMBIA

The Mineral Province of Canada

has produced to the end of 1906, $68,721,103 of Placer Gold; $41,015,697 of Lode Gold, $25,586,008 of Silver; $17,625,739 of Lead; $35,546,578 of Copper; $79,334,798 of Coal and Coke; and $5,813,799 of Other Minerals; or a total of **$273,643,722.** The Mineral Production of the Province for 1906 was

$24,980,546

The Tonnage of Ore mined in 1906 was 1,963,872 tons. The Gold Production in 1906 was $5,579,039 the Lead Output 52, 408,217 lb., and the Copper 42,990,488 lb.

Lode Mining has only been in progress for about 14 years, and not 20 per cent. of the mineral land has been even prospected; 300,000 square miles of unexplored mineral-bearing land are open for prospecting.

The Mining Laws of this Province are more liberal and the fees lower than any other Province in the Dominion, or than any Colony of the British Empire.

Mineral Locations are granted to discovers for nominal fees.

Absolute Titles are obtained by developing such properties, the security of which is guaranteed by Crown Grants.

Full Information, together with Mining Reports and Maps, may be obtained by addressing

HON. MINISTER OF MINES

Or WM. FLEET ROBERTSON, Provincial Mineralogist, VICTORIA, B.C.

Dominion of Canada

Synopsis of Canadian North-West Mining Regulations

COAL—Coal mining rights may be leased for a period of 21 years at an annual rental of $1 per acre. Not more than 2,560 acres shall be leased to one individual or company. A royalty at the rate of five cents per ton shall be collected on the merchantable coal mined.

QUARTZ—A person 18 years of age, or over, having discovered mineral in place, may locate a claim 1,500 x 1,500 feet.

The fee for recording a claim is $5.

At least $100 must be expended on the claim each year, or paid to the mining recorder in lieu thereof. When $500 has been expended or paid, the locator may, upon having a survey made, and upon complying with other requirements, purchase the land at $1 per acre.

The patent provides for the payment of a royalty of 2½ per cent. on the sales.

Placer mining claims generally are 100 feet square; entry fee $5, renewable yearly.

An applicant may obtain two leases to dredge for gold of five miles each for a term of twenty years, renewable at the discretion of the Minister of the Interior.

The lessee shall have a dredge in operation within one season from the date of the lease for each five miles. Rental $10 per annum for each mile of river leased. Royalty at the rate of 2½ per cent. collected on the output after it exceeds $10,000.

W. W. CORY,

Deputy of the Minister of the Interior

"Continuous Coal Cutters"

Sullivan Coutinuous Coal Cutter in Byesville, Ohio, Field, showing method of cutting across the face

The Sullivan Room and Pillar Chain Machine has an efficiency of 50 to 200 per cent. in excess of the breast machine, owing to the following facts :

1. Machine moves across room at any time, without moving jacks
2. Occupies one-half as much space in front of coal. It is not necessary
3. Machine may keep cuts on the bottom and leaves the coal in the best
4. Uses from 20 to 30 per cent. less power per ton of coal cut

The Behrend System

Of Dry Concentration Is Ideal and Economical

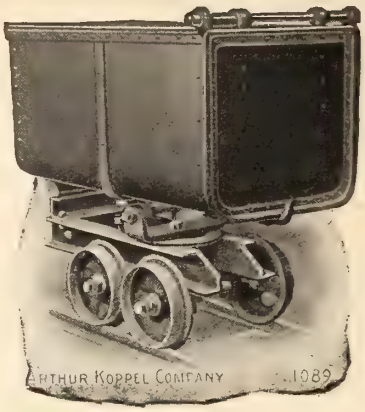
The Behrend Dry Concentrator is a portable and very durable machine, requiring only ½ horse power to operate. Capacity 8 to 15 tons per day, according to sizes of material under treatment, averaging about 12 tons.

Will recover 80 to 90 per cent. of values; is applicable to a wider range of ores and minerals than any other system; requires no skilled labor.

Makes clean separation of zinc and lead sulphides. Works equally well on all sizes from 8 to 100 mesh, and saves the slimes.

Unrivalled as a clean-up machine in placer work, recovering the black sand, gold and platinum.

The usual dust conditions peculiar to dry concentration are entirely eliminated.



WRITE US FOR DESCRIPTIVE PAMPHLET.

LA ROSE CONSOLIDATED MINES COMPANY.

The first annual report of this corporation has recently come to hand. Because of the prominence and importance of La Rose mine itself, if for no other reason, the report deserves more than passing notice.

By intention or through neglect those responsible for the compilation of the document have not complied with several essential requirements of the Ontario Companies Act. There is no excuse for this. It is bad business, and implies defective vision either in the promoters or in their legal advisers, or in both.

As mentioned below there are four directors whose interests in the company is not defined in the report. Subscribers have a legal right to demand full information regarding the holdings of these directors.

Apart from these serious and needless omissions, the report is apparently a sincere attempt to give the public much necessary information.

The publication of the report sets at rest a number of points that have been discussed by the public without official information.

The Consolidated Company controls the following properties: La Rose, La Rose Extension, Princess, Fisher, Eplett, Silver Hill, University Mines and the Violet. All of these properties, with the exception of the Violet, were formerly controlled by La Rose Mines, Limited, which still remains the operating company.

The Consolidated Company has a Maine charter. The capitalization is $7,500,000 in $5 shares. The directors of the company are the five directors of La Rose Mines, Limited, Messrs. John McMartin, L. H. Timmins, N. A. Timmins, D. A. Dunlap and D. McMartin, together with Mr. D. Fasken, of Toronto, and Messrs. E. P. Earle, R. T. Greene, and F. W. Holmes, of New York. Messrs. Earle and Fasken are well known in Canada in connection with the Nipissing mine. The report does not say what interests the four last named directors have in the Consolidated Company, whether they have purchased a part of the La Rose Mines, Limited, or whether they represent the Violet interests, or whether they have been brought into the Consolidated Company owing to their varied experience in connection with the Nipissing mine.

Three reports by mining engineers accompany the general report of the company. The first of these is by Watson & Watson, and is dated June 15, 1908. The senior member of this firm is now resident manager of the Nipissing and is consulting engineer to La Rose Consolidated. The second report is by Mr. T. R. Drummond, recently manager of the Nipissing, and is dated June 1, 1908. The third is by Dr. W. G. Miller, and is dated August 9, 1907. The ore reserves reported

on in all three cases are practically confined to La Rose mine proper, J. S. 14. The most recent report, that by Watson & Watson, shows an estimated profit of $2,017,878, while the net value given by Mr. Drummond is $2,638,950. Dr. Miller's report, made for the original owners a year ago, gives a considerably higher number of ounces; but the net value is indicated only in a general way. For the main vein Watson & Watson give 4,045.4 tons; Mr. Drummond gives 4,957, and Dr. Miller gives 5,966, of which 3,728 tons are above the first level and 2,238 tons below it. Dr. Miller states that the ore averages 765 ounces of silver to the ton on the first level, and he is inclined to allow a higher average value than this for the block of ore lying between the first level and the surface. Analyzing the figures in the reports of Watson & Watson and Mr. Drummond, it is seen that the 4,045.4 tons in the former report contains 2,903,310 ounces of silver, or an average of 717 ounces to the ton; while Mr. Drummond's 4,957 tons contain 3,673,000 or 740 ounces to the ton. It is not so stated, but the 717 and 740 ounces respectively apparently represent the average found for the ore on the first level.

Of the three reports the public will naturally lay more stress on the most recent one as showing what the ore in the mine really represents at the present time. According to Messrs. Watson & Watson this shows an estimated profit of $1,735,712 for practically developed ore and $282,166 for indicated ore, or a grand total of $2,017,878.

The mine has been under development for four years and according to the statement of the president in the report it has earned $1,204,862 net for its owners.

DR. HENRY YOULE HIND.

Dr. Henry Youle Hind, explorer, geologist, journalist and educationist, died at Windsor, Nova Scotia, on Sunday, August 9th.

Born at Nottingham, England, on June 1, 1823, he received his early training at a local grammar school. After two years in Leipsic he studied for some time at Cambridge. In 1846 he came to Canada and accepted the appointment of instructor in mathematics and chemistry in the Provincial Normal School, Toronto. Five years later he became professor of chemistry and geology in Trinity University. This chair he occupied for thirteen years.

In 1857 the Canadian Government requested Professor Hind to accompany, in the capacity of geologist, an exploring party sent to the Red River. In the succeeding year he was placed in charge of a similar expedition to the Assiniboine and Saskatchewan regions. The published reports of his travels contained the first map of that great and fertile country.

Again, under the direction of the Canadian authorities, Professor Hind explored the shores of James and Hudson Bays, and, to a limited extent, the interior of the Labrador peninsula. Much of this was pioneer work of the most difficult and trying nature.

Resigning the chair of geology and chemistry in 1864, Professor Hind undertook a preliminary geological survey of New Brunswick at the request of the Government of that province. After completing this task in 1866, he came to Windsor, Nova Scotia, where he resided until his death.

In the year last mentioned, 1866, the excitement induced by the discovery of gold in Nova Scotia was at its height and Professor Hind was engaged by the Provincial Government to examine and report upon the gold districts of the province. Ten years later he explored northeastern Newfoundland and the Atlantic coast of Labrador, investigating not only the mineral resources of these regions, but also the fisheries and other natural resources.

When, in accordance with the provisions of the Treaty of Washington, the Fisheries Commission met in Halifax in 1876, Professor Hind played an important part in the deliberations. Later, his invaluable work in charting the movements of fish in North American waters won for him a gold medal from the directors of the Paris Exhibition.

In addition to his other activities Dr. Hind was from 1852-1855 editor of the Canada Journal, the official organ of the Canadian Institute. For a time, also, he edited the British American Magazine and the Journal of the Board of Arts and Manufactures of Upper Canada.

Trinity College, in 1853, conferred upon him the degree of M.A., and in 1890 King's College, Windsor, granted him the degree of D.C.L.

During later years much of Dr. Hind's time and energy was devoted to assisting in upbuilding King's College and affiliated institutions.

Dr. Hind was, in one sense, a natural philosopher of the old and most admirable type. He possessed the wide interests, the literary cultivation, the high devotion and the profound faith that marked men like Tyndall, Huxley and Darwin. On the other hand he had all the alertness, directness, and broad commercial sense that are pre-requisites in modern scientific workers.

While he was a voluminous writer, he wrote only from the superabundance of his knowledge and observation. Consequently he wrote little that is not well worth reading.

Those whose privilege it is to have read Dr. Hind's works are forced to marvel at the variety and depth of his attainments. The whole book of nature was open to him as it is to very few of this generation. His whole life is an object lesson. A sound body and a sane mind were his. These, added to high and true ideals, gave to Canada one of the most distinguished scientists of the day.

THE FERNIE DISASTER.

All Canada was shocked when, on August 3rd, newspaper despatches announced that the town of Fernie was wiped out of existence by fire. Exaggerated reports were rife and it was freely stated that the coal mining industry of the Crow's Nest Pass district had received a blow that would cripple it for a long time to come. The loss of life was also the subject of much misstatement.

Latest reports indicate that not more than eighteen lives were lost. The loss of standing timber cannot be computed, although it is known to run up into the millions of dollars. Both the Crow's Nest Pass Coal Company, the C. P. R. and the G. N. R. suffered losses ranging from two hundred thousand to three hundred thousand dollars. The lumber companies' loss totalled about one million dollars.

So far as the property loss in the town of Fernie can be estimated, it appears to approximate seven million dollars.

Only slight damage was done to the mining and other equipment of the Crow's Nest Pass Coal Company. Neither Coal Creek nor Michel suffered. Production was resumed immediately after the fire had run its course. Temporary scarcity of labor is the only deterrant at present. At Hosmer the tipple and principal buildings of the C. P. R. colliery were unharmed. It had been the intention of the management here to commence shipments of coal and coke in December of this year. This intention will be carried out.

The fire swept resistlessly over an area thirty miles long and from two to ten miles wide. Once started no human agency could grapple with it. The conformation of the Elk River valley gave the fire a free hand and a full sweep. Hence Fernie, standing directly in the path of the flames, was destroyed in an incredibly short time.

Hardly a day elapsed between the destruction of Fernie and the arrival of relief from outside sources. The towns and cities of Southern British Columbia telegraphed funds, collected and despatched clothing and food, with astonishing and gratifying promptitude. Winnipeg, Toronto, Ottawa, Kingston and other eastern cities contributed with corresponding speed. The British Columbia Government gave its agents *carte blanche* so far as money and supplies are concerned. The railways transported passengers and freight free of cost from and to the scene of the disaster. The Crow's Nest Pass Coal Company bent all its energies to relief work and contributed a substantial sum of money in addition. Its buildings were put at the disposal of the shelterless, and its officers were prominent in the arduous work of organization and administration.

But most gratifying of all was the generous action of the city of Spokane on the other side of the international boundary. This city was among the first to telegraph money to the sufferers. In this is displayed a spirit that is more than merely praiseworthy, a generosity that is not hedged in by restrictions of nationality. The Canadian nation, as a nation, should make fitting acknowledgement of Spokane's timely help.

THE INTERNATIONAL NICKEL COMPANY.

The sixth annual report of the International Nickel Company is a document of more than passing interest. So complete is this corporation's control of the nickel markets of the world that it has practically no competition. It owns and operates the Sudbury copper-nickel mines. It controls the Nickel Corporation of London and the Societe Miniere Caledonienne of Paris, and through these organizations has been able to make its monopoly almost absolute.

The limited demand for nickel has robbed this monopoly of its sting. The International is constantly striving to find new uses for the metal and thereby to widen the market.

Its efforts have not been unsuccessful. In the last twelve years the United States consumption has grown from 4,000,000 pounds to 20,000,000 pounds per annum.

Unlike other copper smelting companies, the International has not only maintained its earnings but has increased them. Upon its common stock it pays no dividends as yet. Upwards of $5,000,000 has been spent in new construction and general improvement of plant.

For the last fiscal year, ending March 31st, its net profits are announced to be $1,324,742. Expenditure upon construction and equipment amounted to $1,548,-481; for depreciation of plant the sum of $215,975 was allowed; for exhaustion of minerals, $94,351, and $168,250 for bond sinking fund. After payment of bond interest and a 6 per cent. dividend on preferred stock, the sum of $790,000 was added to surplus, and $300,000 added to the property depreciation allowance.

The International Nickel Company appears to be one of fortune's favorites. It is interesting to speculate as to what its net profits would amount to if present conditions were so altered as to permit and encourage competition in the smelting of copper-nickel ores in Ontario.

ENTER NEW ZEALAND.

A New Zealand coal mining concern is seriously contemplating the possibility of entering into competition with the Vancouver collieries.

We had occasion lately to allude to the high prices maintained by the collieries operating in Vancouver Island. The fact that competition from New Zealand is even imaginable does not speak well for the spirit that animates the Vancouver Island operators. Our conviction is that the price at which coal is sold in Western British Columbia could be lowered fifty per cent. and still leave a sufficient profit.

THE GREAT WAIHI MINE.

Written for The Canadian Mining Journal by J. M. Bell, Director of the Geolagical Survey of New Zealand, and Colin Fraser, Mining Geologist.

INTRODUCTION.

In a graphic article in the Mining and Scientific Press, on "The Great Gold Mines,"* Mr. T. A. Rickard includes the Waihi Mine of New Zealand in the world's sixteen great gold mines, and mentions that the choice for the premier position among these rests between the Robinson Mine of the Transvaal and the Waihi. In the concluding remarks of the article he places the Waihi second to the Robinson only on the score of the larger, definitely-ascertained ore reserves in the latter.

The Waihi Mine is situated within the limits of the town of Waihi, in the Hauraki Mining Division, Auckland Province, New Zealand. The mine lies in an easily accessible locality, some seventy miles southeast from the city of Auckland, the metropolis of New Zealand, with which it is connected by rail.

The Martha lode, which is the vein of most conspicuous outcrop in the Waihi District, was discovered in 1878. The initial operations on the Martha lode by the original prospectors, and by the Martha Gold Mining Company subsequently floated, were not successful. In 1890 the Waihi Gold and Silver Mining Company, Limited, which had been formed in 1887 to work the Amaranth lodes, bought the Matha Company's property for £3,000. Even this venture can hardly be said to have met with great success till the inauguration of the cyanide process in 1894. Since that date the rise of the Waihi Mine from the rank of an insignificant prospect to that of one of the foremost gold mines of the world has been rapid and consistent.

The area held by the Waihi Company amounts to 765 acres. This area covers not only the Waihi Mine proper located on the Martha lode and adjoining veins, but also the Silverton, Union and Amaranth veins on the Silverton Hills, which are, however, not being worked at present, and are consequently not considered in this article. Continuous along the line of strike of the Martha lode, in a general northeasterly direction from the Waihi Company's property, are in succession the holdings of the Waihi Grand Junction, the Waihi Extended and the Waihi Consolidated companies, while a separate holding of the first-named company bounds the Waihi Mine to the westward.

General Physical Geography.

The workings of the Waihi Mine are situated on the slopes of Martha Hill, on the slopes of the Silverton Hills, and beneath the stretch of flat-lying ground half a mile wide between these two physical features. The Martha and the Silverton Hills stand at the northern edge of the gently rolling Waihi Plain. This plain, which is about seven miles from northwest to southeast, and rather more than four miles at its greatest extension in the opposite direction, has an altitude of about 280 feet above sea level, and is surrounded by low hills, showing smooth slopes and few rock ledges. The hills are continued northward from Martha Hill as the mountainous, densely forested country, which forms the backbone of the Hauraki Peninsula. Martha Hill is connected with this elevated country by a ridge, which may be spoken of as the Martha ridge, rather lower in altitude than the hill itself. The Silverton Hills are low features forming outliers from the mountains, within the plain. The relatively extensive Waihi Plain, through which meanders the Ohinemuri stream, represents topographically an old lake basin. Formerly the Ohinemuri flowed to the east coast of the Hauraki peninsula, but the damming of its course in that direction by a rhyolite flow resulted in the development of the lake above mentioned. The basin now drains westward through the wild and beautiful Karangahake gorge to the valley of the Thames. The plain is covered only by low manuka scrub, of little commercial value save as firewood, but the more elevated country is forested with larger trees eminently suitable for mine timber.

General Geology.

The oldest rocks that can be inferred to exist in the Waihi goldfield are argillites and grauwackes of Jurassic and pre-Jurassic age, which form the basement series of the whole Hauraki peninsula. Since, however, no outcrop of these sedimentaries has been located within a radius of twenty-five miles of Waihi these rocks may here be regarded as comparatively deep seated.

Tertiary volcanics comprising dacitic, andesitic and rhyolitic lavas and pyroclastics, form the whole of the superimposed rock complex.

The oldest of the volcanics exposed in the Waihi area are dacitic lavas which were ejected upon an old land surface of argillites and grauwackes probably when the land stood at a considerably higher elevation than at present. These dacites, which are the rocks in which the gold-silver bearing veins occur, have but a very limited areal extent at the present surface, since they are in great part covered by the younger volcanics to be later described. In the locality under description outcrops of the vein-bearing dacites are to be seen only in the Martha hill and ridge, and on the Silverton Hills. Wherever encountered, they are highly altered by hydrothermal metamorphism. On the surface they are often weathered to a soft, unctuous clay-like material. The effects of hydrothermal alteration are especially apparent in the neighborhood of the various veins, where the dacites, though hard, are almost completely propylitized and seamed by stringers of calcite, quartz (both chalcedonic and highly crystalline), orthoclase (variety valencianite), in minor amount, and pyrite.* The vein-bearing rocks have been described as rhyolites,† but careful chemical and petrographical investigation have led the writers of the present paper to classify them as dacites.

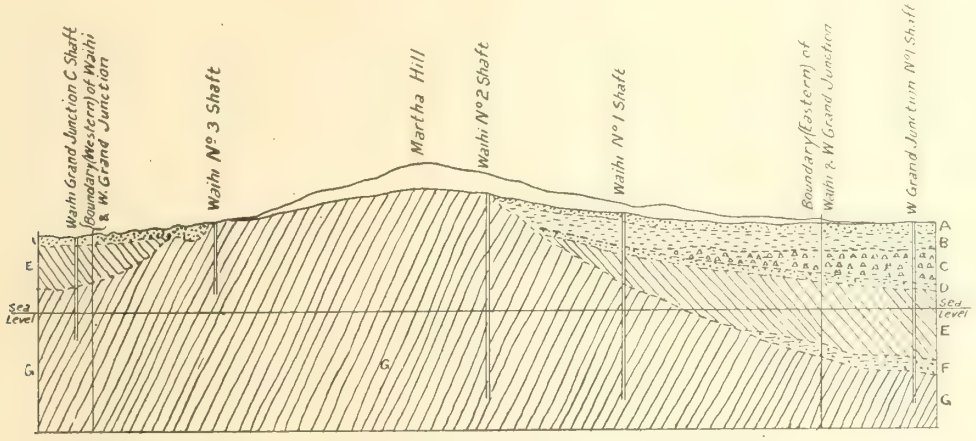
Younger andesitic and dacitic lavas and tuffs overlie an irregular surface of the vein-bearing dacites. They form the higher hills in the vicinity of the town of Waihi, and in places occur intercalated between the vein-bearing dacites and the rhyolitic flows of the Waihi plain skirting the Martha and Silverton Hills.

Unconformity between the older vein-bearing dacites

*"Mining and Scientific Press," San Francisco, 4-5-07, p. 565.

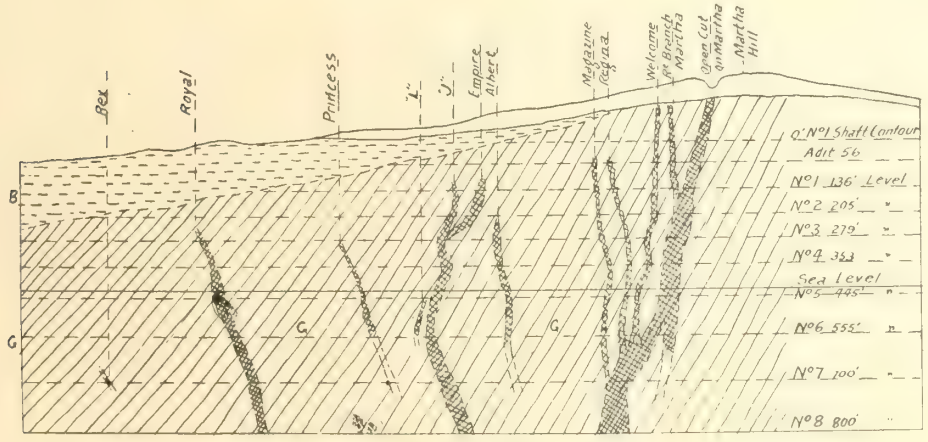
*See paper by Waldemar Lindgren, Engineering and Mining Journal, New York, Feb. 2, 1905.

†"Rocks of Cape Colville Peninsula," Sollas & McKay, Vol. II., 1906, pp. 67-68.



and the younger semi-basic volcanics is shown by an old land surface pierced in the Waihi Grand Junction shaft at a depth of 630 feet below the surface of the plains or 180 feet below sea level, where the occurrence of silicified carbonized tree trunks indicates former sub-serial conditions. The period of vulcanism to which these younger semi-basic rocks are referable was probably followed by a comparatively long period of quiescence, during which the country was deeply dissected by the Ohinemuri and its tributaries.

Subsequent to this dissection, volcanic activity preceded or accompanied by a considerable subsidence resulted in the extravasation of the rhyolitic lavas, which have very considerable development in the Waihi area. Three distinct petrological types are recognizable among these acidic volcanics. These, named in order of succession, are: (a) spherulitic rhyolite, (b) brecciated pumiceous flow-rhyolite, locally called "Wilsonite," and (c) gray lithoidal rhyolite. The spherulitic rhyolite forms the high bare hills not far from the town of Waihi, and the ridges extending therefrom to the eastern coast line. The peculiar, brecciated, pumiceous flow-rhyolite broken through and overlain in places by the gray compact flow-rhyolite, has filled in the old basin or ponded valley of the Ohinemuri before mentioned, and forms the surface rocks of the Waihi plain.



The loosely consolidated sands and gravels along the various streams consist of material derived from both the semi-basic and acidic volcanics.

The Martha Vein System.

As already remarked, the Waihi mine started its splendid course on the outcropping Martha lode. Now, that ore-body is but one of the many which comprise the complicated and branching series forming the Martha vein system. Some of these veins reached the surface, but, being covered by the layers of rock waste which is almost everywhere present, did not actually outcrop, while others were discovered only as the workings of the great mine advanced downward to the present lowermost level—1,000 feet from the surface—and on being worked upwards were found to feather out in the enclosing rock.

(Excepting Edward Vein which is Parallel to Section)
Scale 330' = 1 inch

The Principal Veins.

Altogether, some sixteen veins of the Martha system have in the past contributed or are still contributing to the output of the Waihi mine. The position of all of these veins and their relation to each other may

be seen by referring to the general plan of the Waihi Company's property. The separate plan of the veins being worked at the 700-foot level shows the connection between the several veins at that depth below the surface. The more important producers are the Martha, Welcome, Regina, Magazine, Edward, Empire, Royal, and Albert. Owing to the many remarkable variations exhibited by all of these veins certain somewhat burdening details appear necessary to their description.

The Martha Vein.—The Martha lode, the earliest ore-body to be worked, is still a very important producer, and so far shows, in descending, increasing width and no diminution in quality of pay ore. The vein, which has a general north-north-easterly trend, dips to the southeast at varying angles approximating 75°.

The Martha is traceable throughout the Waihi Company's mine for a distance of 3,400 feet, and it also extends into the property of the Waihi Grand Junction Company. From the latter company's mine a branching reef—the Junction No. 2—is continued into the Waihi extended claim, and thus a longitudinal extension of almost a mile of continuous quartz is proven along this remarkable vein. In the Waihi Company's property at the 136-foot level,* the Martha gave payable ore for a length of 1,100 feet, while in the 850-foot level it has yielded payable ore for 1,200 feet in the northeastern part of the Company's property with very low grade vein material along its west-southwest extension. In the 850-foot level there still remains some 300 feet of an unproven block from the present face of the north-easterly drift on the vein to the boundary of the Grand Junction property. This block is probably payable since the vein shows good ore where it enters the Grand Junction at this level. The pay shoot of the Martha lode has apparently a high pitch towards the northeast from the surface to at least as far downward as the 850-foot level.

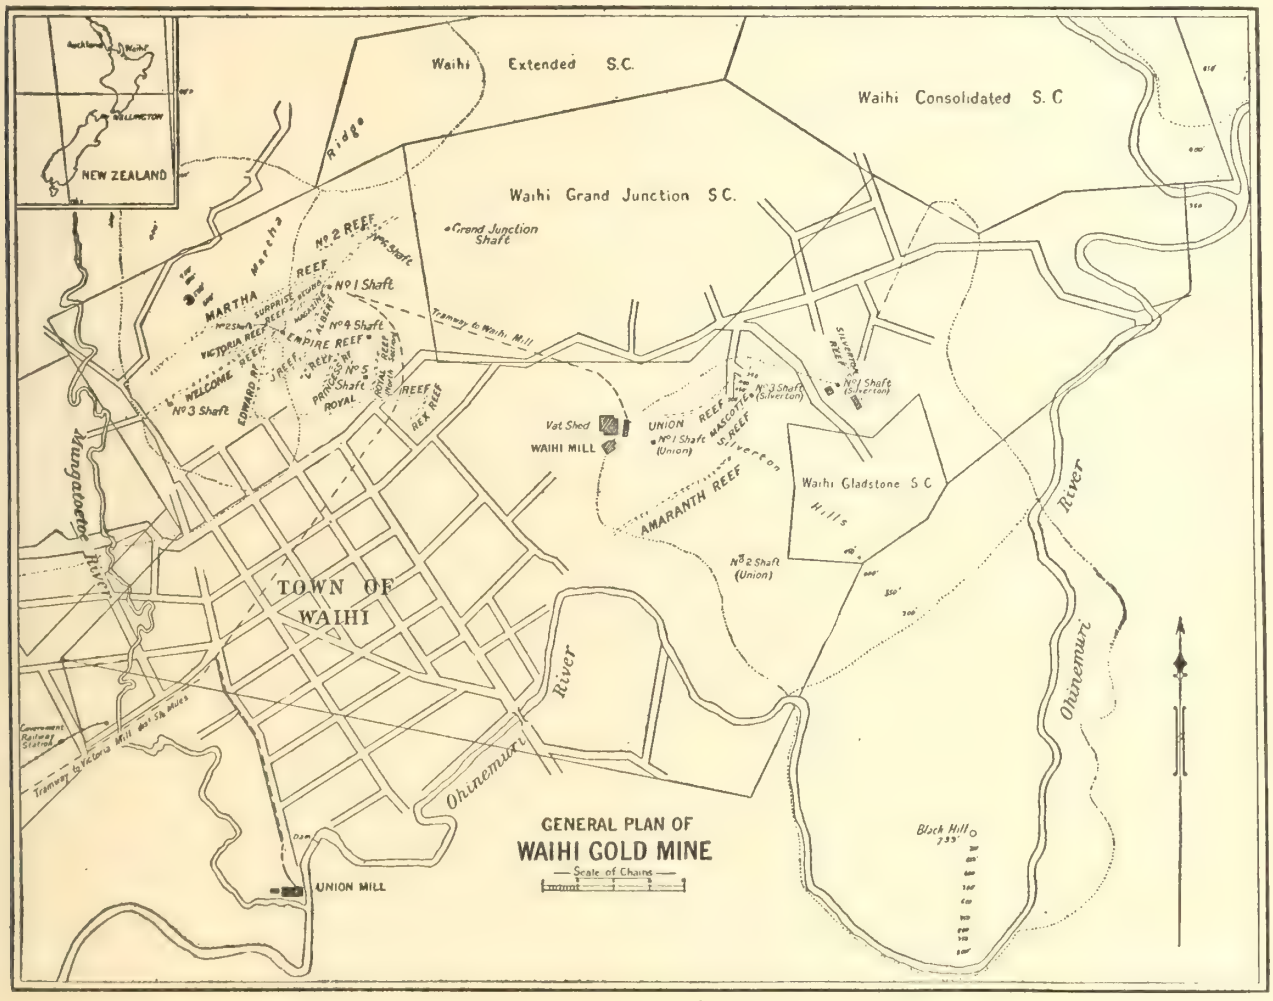
At the surface the Martha varied in width from 5 feet to 50 feet with an average of 25 feet, while in the 850-foot level it varied from 20 feet to 120 feet, with an average of 67 feet. This greatest width of vein material occurs after the Welcome, Regina and Magazine have joined it on the dip to form practically one continuous vein. In the newly opened 1,000-foot level excavation has not yet proceeded sufficiently far to prove the Martha or any other vein of the system.

In the upper levels of the mine where the ore was mainly oxidized the Martha was payable from foot-wall to hanging-wall, but lower down the values were chiefly confined to the rich sulphide portion along the foot-wall. Still lower down on the Martha below the junction of the Regina and the Magazine at the 700-foot level, the values occurred mainly on the side on which these veins joined, namely the hanging-wall. Where the Martha is widest, namely, 120 feet, only about 50 feet afforded pay ore. In the 136-foot level a few feet of rich sulphide ore appeared in places on the foot-wall. Thence downward, level by level, the sulphide portion increased in thickness, and from the 445-foot level became the principal ore. In the 555-foot level the oxidized ore ceased to be conspicuous, and in the 850-foot level it has practically disappeared.

The average value of the pay ore from the Martha, according to the mill returns, has preserved a striking uniformity from the outcrop to the greatest depth yet attained (850 feet), that is, through a vertical height of 1,055 feet. This value is approximately £2 14s. 0d. per ton (2,000 pounds).

Welcome Vein.—The Welcome vein is traceable from the surface to and below the 850-foot level. From the 279-foot level downward it meets the Martha in a junction pitching in a south-westerly direction, along the inclination of the Martha. Thus its longitudinal extension diminishes from level to level when followed downward. The Welcome is disposed almost vertically, although in places where it approaches the Martha it dips slightly towards the latter, that is, to the northwest. Its general trend is slightly more northerly than the Martha. In the uppermost level of the mine, the pay-shoot of the Welcome was not less than 1,350 feet long, and the vein was traceable for quite 2,200 feet. The payable ore, however, diminishes in longitudinal extension in descending, and at the 850-foot level extends for only 250 feet in length westward of its junction with the Martha. At the surface the Welcome averaged about 20 feet in width—all payable ore, while at the 850-foot level the vein averages quite 75 feet and varies from 20 feet to 100 feet. Even where 100 feet wide the vein is nearly all payable ore, only about 10 feet of stone occupying a median position being unpayable. This low-grade material forms a convenient pillar between the two payable portions which are being stoped separately.

Regina Vein.—The Regina, which is a much less prominent vein than the Martha or the Welcome, did not appear at the surface and was discovered only at the 279-foot level as a branch of the Welcome. From this level it was traced upwards to the 136-foot level. Dipping at a high angle in a north-westerly direction towards the Welcome, it becomes part of this larger vein throughout its course at the 700-foot level. As the north-eastern part of the Welcome at this level junctions with the Martha, the Regina also forms part of the latter, though, in stoping, the ore is reported as coming from the Regina section of the Martha. The Regina vein material is nearly all payable ore and of rather higher average value than that of the Martha. In the 279-foot level the vein varied in width from 1 foot to 15 feet, and averaged quite 7 feet for the 550-foot stope length of the pay-shoot.



Magazine Vein.—The Magazine, like the Regina, is an off-shoot of the Welcome from which it branches at the 205-foot level. It dips at an angle of 75° in a north-westerly direction towards the Regina, Welcome and Martha, uniting in dip with all of these at the 700-foot level to form the great mass of vein material in the Martha at and below that level. The length of the Magazine at the 279-foot level is about the same as the Regina. It varies in width from a line to 15 feet, and averages quite 8 feet. The ore in the vein is all low grade, assaying in gold not more than 8 dwts. to the ton at the higher levels and as low as 5 dwts. near its junction with the Regina at lower levels.

Edward Vein.—The Edward vein is in some respects the most remarkable and interesting vein of the whole Waihi system. It was discovered only at the 700-foot level on driving west along the Empire, but was afterwards traced upwards to a point 40 feet above the 445-foot level, at which point it feathers out to zero. The vein, which runs nearly north and south, connects the Welcome with the Royal. In the 700-foot level the pay-shoot has a length of 750 feet and a width

*All the levels are measured from the collar of No. 1 shaft which is 426 feet above sea level and 205 feet below the original summit of Martha Hill or the highest point of outcrop of the Martha lode.

varying from 3 feet to 18 feet. In the 850-foot level the vein has improved greatly both in dimensions and ore-values. It varies in width from 27 feet to 92 feet, and its average is certainly not less than 54 feet. At its point of maximum width—some 250 feet south of its junction with the Welcome—the vein bifurcates, 16 feet of material forming the eastern and 6 feet the western branch. These two branch veins themselves fork, the larger forming two veins, 16 feet and 15 feet wide respectively, the smaller, two veins each 6 feet wide.

In the 700-foot level the Edward dips to the north-west at a high angle, but in the 850-foot level where the vein is widest, the great ore-body appears like an inverted wedge, the two walls dipping respectively to

the east and to the west. Practically all the vein material of the Edward constitutes highly payable ore, and in some places is of bonanza richness. On the 850-foot level at its junction with the Empire, where it is 75 feet in width, the ore values average no less than £10 10s. 10d. to the ton.

Since the Edward is connected with the Martha through the Welcome, and since, as already mentioned, the chief values of the Martha at the 850-foot level are confined to its north-eastern part, together they form a continuous wide band of highly payable stone from a point near the Royal to, and possibly beyond, the Waihi Grand Junction boundary.

Empire Vein.—The Empire vein may be considered as an eastern branch of the Welcome and of the Edward at horizons above and below the 555-foot level respectively. It first appeared in the 136-foot level and was there stoped for a length of 300 feet, while in the 850-foot level the pay-shoot has been already proven for a length of 1,150 feet. The course of the vein from its junction with the Welcome and Edward is a little south of east. The inclination of the vein presents a peculiar warped effect: on its eastern extension its dip is about 72° to the north; near its middle course, where influenced by junction with the Albert, it is almost vertical; and further westward on approaching its union with the Welcome and Edward, its dip is about 60° to the south. The average width of the vein is 6 feet at the 136-foot level, and increases gradually to about 25 feet at the 850-foot level. The whole of the vein-stone from wall to wall within the limits of the pay-shoot is milling ore.

The Royal.—The Royal vein was discovered at the 353-foot level, and is traceable upwards for 50 feet above the 279-foot level, at which point the drifts and stopes run out against the non-mineralized rhyolite which overlies at this point the vein-bearing dacite. At the 279-foot level the pay-shoot was somewhat over 300 feet in length, while at the 850-foot level this dimension has risen to 1,400 feet. The vein trends almost east and west and dips to the northward at 76°. The average width is about 10 feet at the 279-foot level, and, gradually increasing downward, is not less than 17 feet at the 850-foot level.

The Albert.—The Albert vein, discovered in the 205-foot level, extends downwards through all the workings. Its general trend is about north-northeast, and its dip is to the westward at a high angle. The Albert has yielded good ore from the 205-foot to the 555-foot level, but is one of the few veins of the Waihi which has shown in descending, values inferior to those of the upper levels.

Output of the Various Veins.—The following tabulation note showing in what proportion the various veins of the Waihi mine contributed to the total output in the year 1907, is of interest:

Vein.	Tons (2,000 lbs.)
Martha	177,800
Royal	46,645
Empire	45,660
Welcome	43,539
Edward	13,239
Albert	12,231
Regina	4,339
Victoria	3,871
Princess	3,076
Magazine	2,252

The Vein Material.

The vein material of the Waihi mine may be broadly divided into four types, which, for convenience, will be discussed separately:

(1) Sulphide ore.
(2) Non-payable vein filling.
(3) Oxidized surface vein material.
(4) Surface sinters.

(1) The sulphide ore which is now almost the entire source of the mine's wealth, as already remarked, appeared in the 136-foot level of the mine, and has increased rapidly in quantity in each successive level though there is still a very little oxidized ore at the 850-foot level. The sulphide ore consists of two rather indistinct varieties, namely, the banded ore and the replacement ore. The replacement ore, which seems to have been in greater part the original material formed, consists apparently of highly mineralized country rock. So intense has been the mineralization that the original nature of the rock has been entirely lost save in rare cores in the vein material. The replacement ore is mainly quartz of a general greyish or pale greenish color, and of finely crystalline or of finely saccharoidal texture. Through this is disseminated in individual grains, bunches, or tiny irregular veinlets, sulphide material consisting of pyrite, argentite, spalerite, and rarely of galena and chalcopyrite. The greenish color of the quartz is due mainly to chlorite, or some similar mineral. Druses, showing small hexagonal crystals of quartz, occur but are rare. Calcite is an occasional constituent, and there is evidently some manganic carbonate present as judged by coatings of black oxide in the oxidized ore.

The banded sulphide ore, which is always rich, shows narrow wavy bands consisting almost entirely of sulphides intercalated with others of finely crystalline quartz of milk-white colour, or tinted greyish or faintly blueish by disseminated sulphides. The banded sulphide ore occurs in narrow veinlets of irregular vertical and lateral dimensions within the replacement ore. The phenomenon of crustification is generally apparent in the veinlets, bands of quartz and sulphides being arranged on either side and not infrequently with drusy quartz in the middle. Visible electrum occurs in connection with the sulphide ore, but is not common. Ruby silver and wire metallic silver have also been found in the sulphide ore, and some selenium mineral occurs, as evidenced by the presence of that element in the bullion.

It is interesting to note that the gold values occur mainly in pyrite, and to a less degree in the rarer minerals in galena and sphalerite, as proved by analyses. An assay made at the office of the metallurgist of the Waihi Company, of one of the dark bands in the sulphide ore from the 850 ft. level, showed gold to the value of 7.25 ozs. to the ton, and silver to the value of 870 ozs. to the ton. The proportion of silver to gold is exceptionally high in this sample, as judged by the average fineness of the total bullion out-turned, in which the proportion of silver to gold is as 100 to 15.

(2) The non-payable vein filling consists partly of altered dacite and partly of quartz and calcite, through all of which more or less pyrite occurs, though the other sulphides are rare or wanting. Calcite is comparatively rare in the upper levels of the mine, though platy or rhombohedral quartz which is pseudomorphous after that mineral, testifies to the former occurrence of calcite in great quantity. The secondary quartz of this nature is often only a framework of the original calcite, and is consequently exceedingly powdery. This characteristic renders the separation of the non-payable material from the rich sulphide ore in places a matter of difficulty, especially on the Martha vein in the Grand Junction Mine. The original quartz of the non-payable ore is generally milk-white in colour and more closely crystalline than that of the sulphide ore. It is very rarely amethystine in character.

(3) The oxidized vein material represents the oxidized equivalents, both of the non-payable vein filling and of the sulphide ore. At and near the surface in the Martha lode all of this oxidized material was payable and that on the foot wall highly so. The highly payable oxidized ore of the Martha is the result of oxidation and consequent slight surface enrichment of the pre-existing sulphide ore; while the poorer hanging-wall ore contains its relatively low values, as the result of the concentration by descending oxidizing waters, of the gold and silver contained in the small amount of sulphides disseminated in the original hanging-wall vein material. The hanging-wall material is almost entirely oxidized as far down as the 555 ft. level, while, as already mentioned, sulphide appears on the foot wall at the 136 ft. level, and, increasing in width at each successive level, has almost completely replaced the rich oxidized ore on this side at the 555 ft. level. Below the 555 ft. level the hanging wall vein material, exhibiting less and less oxidation, has not been subjected to the enrichment specified and is therefore low-grade, and passes down into the non-payable vein filling. The latter nearly always contains a little gold and silver, and shows in places oxidation along fractures even to the 850 ft. level. In addition to the Martha, the Empire and the Welcome both showed rich oxidized ore.

The oxidized vein material is generally rusty and in many places blackish with hydrous oxides of manganese. Free gold is rarely visible, even in the richest material

though, finely disseminated, it exists in considerable amount. At the surface films of leaf gold were not uncommon in the joint planes. The quartz associated with this oxidized material shows fine crystalline, saccharoidal and platey structures. An assay made of a sample of rich oxidized ore from the Martha lode gave an analysis by Mr. P. G. Morgan, of the N. Z. Geological Survey, the following result*:—

Moisture at 100° C.	.26%
Loss on ignition	1.60
Silica	89.98
Ferric oxide	5.62
Alumina	1.82
Manganese and nickel oxides	.39
	99.67

Gold, 2 ozs. 5 dwts. 17 grs. per long ton.
Silver, 10 ozs. 2 dwts. 12 grs. per long ton.

The oxidized surface material on the Martha cannot be considered in the light of what is ordinarily called a gossan or cap of concentrated metallic minerals. The quartz was merely stained with iron and manganese oxides. There were no deposits of these minerals, and the values in gold and silver, even in the richest oxidized foot-wall ore, were little, if at all, higher than obtained in depth in the sulphide ore. Merely an oxidized surface capping of limited extent occurred, indicating that there has been time for little oxidation since the outcrop of the lode was laid bare.

*Transactions Australasian Institute of Mining Engineers, Volume VIII., page 182.

(4) The surface sinters, which frequently exhibit a banded structure, consist of a very finely crystalline or crypto-crystalline quartz, either whitish and opaque with rusty stains along the joint planes, or of a general pale rusty or pinkish colour.

The walls of the Waihi veins are in general fairly well defined. Owing to the fact, however, that much of the vein material of the Waihi Mine is merely metasomatically replaced country rock, there is in places no decided demarcation between wall-rock and vein material, but rather a gradual transition from payable vein material to propylite containing little or no values. Indeed, in such cases, what is to be classed as ore is often determined only by assay.

In many parts of the mine all of the several vein fillings show brecciation, and even fissuring, but faults of any magnitude giving serious displacements do not occur.

It is noteworthy that the vein material in general of the Waihi Mine bears a striking resemblance to that of the Redjang Lebong Mine in Sumatra, where the geological conditions are, it is understood, closely similar. A resemblance to the vein filling of the de Lamar Mine, Idaho, has also been cited by Waldemar Lindgren, while J. E. Spurr refers to P. G. Morgan's mention of the resemblance between geological conditions at Waihi and Tonopah, Nevada.*

(To be continued.)

Summary Report of the Mines Branch of the Department of Mines for the Year Ending March 31st, 1908.

The Summary Report outlines the work performed by the Mines Branch of the Department of Mines for the fiscal year ended March 31, 1908.

Dr. Haanel received his appointment as Director of the Mines Branch in May, 1907. By an Order in Council, dated June 19, 1907, Mr. John McLeish was transferred from the statistical office of the Geological Survey Branch to the Mines Branch. Later, a part of the chemistry section was similarly transferred. Messrs. T. Denis, F. G. Wait, M. F. Connor and W. W. Leach, officers of the Geological Survey, were also moved to the Mines Branch.

Iron Ore Deposits.

The most important field work performed during the year was the investigation of iron ore deposits in various parts of the Dominion.

Mr. Einar Lindeman was instructed to examine such of the iron ore deposits of Vancouver and Texada Islands as are favorably situated in regard to transportation, and to devote especial attention to the more promising of these.

With the exception of the bog ore deposits at Quatsino Sound, and a small deposit of hematite on Salt Spring Island all the properties visited showed magnetite all in the immediate vicinity of or in contact with crystalline limestone where the latter is in close proximity to igneous rocks. These magnetites are high in iron, do not exceed 0.05 per cent. phosphorus, but are also, as a rule, high in sulphur.

Vancouver Island.—In the Gordon River District, sixty miles from Victoria on the west coast of Vancouver Island, some promising prospects were noticed. The country rocks are chiefly crystalline limestone and igneous rocks, granite and diorites. About seven miles from salt water an outcrop of magnetite has been traced for 350 feet. In several places the ore is in sharply defined contact with granite. Ninety feet below this contact a tunnel, 114 feet long, has been run directly into the hill. It is in ore throughout its length, excepting where a diorite dike, eight feet wide, intrudes. The character of the ore is shown by the following analysis of an average sample taken along the tunnel:

	Per Cent
Silica	8.88
Iron	58.30
Sulphur	[illegible]
Phosphorus	0.013

A sample from another claim, farther up the valley gave this result:

	Per Cent.
Silica	4.51
Iron	67.09
Sulphur	1.60
Phosphorus	0.009

At Head Bay, on Nootka Sound, four outcrops of magnetite occur along a contact of crystalline limestone and diorite about a mile from the bay. At one place the ore body is fifty-five feet wide. The following analysis shows it to be of excellent character:

	Per Cent.
Silica	6.10
Iron	66.17
Sulphur	0.017
Phosphorus	0.016

Mr. Lindeman has serious doubts as to the extent of the Quatsino Sound bog ores. However, he recommends systematic drilling.

Seven miles up the Klaanch River an exposure of magnetite extends along the river bank for 180 feet and is from 25 to 30 feet high. No work has been done. This and other outcrops gave good analyses. Magneto-metric survey indicated other large bodies. Other considerable bodies were found on the Quinsam River.

Texada Island.—The principal ore deposits of this island are in the Prescott, Paxton and Lake properties. The Prescott has been worked more extensively than any other. During several years magnetic ore has been shipped from this property to Irondale, Washington. The ore outcrops about 850 feet from the shore, in a bluff on the brow of a steep hill, at the contact between granite and crystalline limestone. The deposit has been opened at three levels. An open cut shows a face of magnetite forty feet wide and one hundred feet high. Here the ore shows patches of calcite and fragments of brecciated volcanic rocks. Small amounts of iron and copper sulphides are also present. The ore dump gave the following analysis:

	Per Cent.
Insoluble	6.46
Iron	62.57
Sulphur	0.403
Phosphorus	0.024

The ore bodies of the Prescott are of great magnitude.

At the Paxton mine, 3,500 feet east of the Prescott, an outcrop of magnetite occurs directly in contact with granite. The ore is rich, but, like the Prescott ore, shows traces of copper, and is somewhat high in sulphur, though by no means prohibitively high.

The Lake mine, east of the Paxton, shipped 1,000 tons of ore last summer. The ore bluff is 80 feet high and 100 feet wide on the surface. Crystalline limestone forms the footwall, and diorite overlies the ore in places. An open cut shows good clear magnetite.

Coke carrying 15 to 20 per cent. ash is obtainable on Vancouver Island. This ash could be very much reduced by washing the coal. The ash is low in phosphorus.

Exceptionally pure limestone is obtainable at many localities.

Cheap transportation of raw materials is assured by the proximity to tide-water of all the more important deposits of iron ore, fluxes and fuels.

In addition to Mr. Lindeman's report, the following monographs are in preparation: "On Chrome Iron Ore Deposits of Eastern Townships," by Fritz Cirkel, M.E., and "Report on the Iron Ore Deposits of Western Ontario," by F. Hille, M.E.

Part I. of Dr. J. E. Woodman's report on the iron ore deposits of Nova Scotia is in the press, and reports on the iron ore deposits along the Ottawa and Gatineau rivers.

Electric Smelting.

Progress in electric smelting is confined at present to the production of high class steels. Both the Heroult and the Kjellen furnaces are being enlarged. The electric process is gradually displacing the crucible process in the manufacture of high grade and alloy steels.

The Lash Steel Process.—The Lash Steel Process, in which finely divided ore is intimately mixed with carbon, a certain quantity of finely divided carboniferous iron, sawdust and suitable fluxes, and the whole treated in an open-hearth furnace in a bath of molten metal, is one of the most recent inventions. It is claimed that in using the Lash mixture in an electric furnace no bath of pig iron is necessary, and a yield of 98 per cent. of the metallic contact of the mixture is recorded.

A typical mixture, all of which is finely divided, is as follows:

Iron ore	54
Cast iron borings	27
Sawdust	4
Limestone	4
Coal tar	3
Coke	8
	100

If the average cost of producing one ton of ingots in the regular open hearth be taken as $20.79, the corresponding cost for the electric furnace, using the wash mixture is $16.22.

Other Work.

The results of Mr. Erik Nystrom's investigation of the utilization of peat have already appeared in a recent special pamphlet.

The hand-book dealing with the mining and metallurgical industry of Canada is soon to be issued. It will appear annually with necessary revisions. Only producing mines and metallurgical plants in actual operation have been reported upon.

For more than a year Dr. J. B. Porter, Mr. H. F. Strangways and Mr. C. Landry, all of McGill University, have been conducting for the Mines Branch a systematic investigation of the coals of the Dominion. A complete report is expected before the end of next year.

Mr. John McLeish's report on the work of the statistical division makes interesting reading. Mr. McLeish urges the standardization of statistical methods throughout the Dominion.

Other features of the Summary Report we are not now able to take up. The report indicates a decided activity and progress on the part of the Mines Branch. But as an official document it does not show evidence of sufficiently careful editing. In arrangement it is loose. Certain sections are carelessly worded. For these faults there is the excuse of haste. But it would, we think, be in keeping with the dignity of the Mines Branch to see that these failings are remedied.

THE LARDER LAKE DISTRICT.

H. E. T. HAULTAIN.

> "It is always an unexplained wonder how the public tolerates these wild-cat promoters. Many hard-headed business and professional men who have all their life been building up and caring for their reputations, have allowed them to be prostituted in these wild-cat prospectuses."*

An investigation into the psychology of the enterprises connected with this district would be of more value to the public than anything that can be said concerning its geology. It was an ideal field for the wild-catter, and this was taken advantage of most skillfully. Only the general slump saved us from an extensive and disastrous boom in gold shares.

Ontario's appreciation of the relations of otherwise honest men to wild-catters is sadly in need of adjustment. The public's understanding of the mining engineer's philosophy (which indeed ranks with the doctor's and far above the lawyer's) is misled by these wild-cat prospectuses and their prostituted supporters. Some day, some man, altruistic and clean-minded, will explain clearly and persistently to the Ontario public, in a way that it will understand, that mining is not only founded on science, but is a difficult art based on experience, and that the main ingredient of the mining engineer must be honesty. Until this is done, until this is absorbed, or, rather, assimilated, Ontario will continue to look for booms and continue to put a premium on wild-catting.

Larder's early days were characterized by wild-cat promotions of a very clever kind. Some of the prospectuses were the cleverest issued in Ontario. One in particular stands out for the completeness of its non-essentials and the subtle evasiveness of its misrepresentations. Its title page contained the names of some of our best-known professional and business men as directors. It was complete with its bankers and solicitors and its "consulting engineers." But it contained no vestige of reliable information in regard to its ore bodies. Such reference as was made to these was purposely misleading. To anybody with even a slight acquaintance with mining, it was a most palpable fake. The company had territory and nothing else. One cannot blame the public for buying shares in companies supported by the names of good men, but most unhesitatingly must we condemn the action of men who lend their names to such wild-cat promotions, and it is high time that reputable engineers took steps to condemn publicly as wholly unprofessional (and consequently unreliable) engineers (alleged?) who allowed their names to stand on such prospectuses.

This wild-catting was so prominent a feature of Larder Lake that the whole district received a black eye, and it was hard to make anybody appreciate the fact that any good could exist up there. The arresting of Law and the letting him out on thirty thousand dollars bail had a wholesome effect towards educating the public, but did not help the district. Now, however, some of the men who helped the wild-catters find themselves with unprospected claims on their hands, and are rising to their responsibilities with honest intention in their efforts. Besides the wild-catters, there have been a few individuals and at least one company that have been working more or less steadily, and the whole district has now a much healthier tone.

The Ontario Bureau of Mines has issued an excellent report by R. W. Brock on the district, much of which has been published in the Canadian Mining Journal (January 1st and 15th, 1908). There is really but little to be added to this report, except to emphasize some of the matters that Mr. Brock hints at. The main feature of the district is the belt of serpentinized dolomite (?) extending in an east and west direction for at least 12 miles, and probably further. This belt contains a fractured zone in which the network of fissures has been filled with quartz. The zone varies in width up to several hundred feet, and the quartz stringers themselves range in thickness from a knife-edge up to six inches or so, and occasionally a mass of quartz up to twelve or fifteen feet in width is met with. There are also well defined veins of quartz, but the network is the main characteristic of the district. At various points along the whole 12 miles of this zone visible gold has been found in the quartz, and in at least two claims very rich specimens have been taken out. The combination of wide ore bodies and occasional rich specimens was the ideal condition for the wild-catter, and even now the sight of these specimens never fails to stimulate even the most disappointed of the wild-catter's victims. Today the general mental attitude of most of those associated with the district is a gloating over these specimens, coupled with an unconscious (though really wilful) ignorance of the true values of the ore bodies outside of the specimen areas. It is true that several tons of rock have been sent outside to be tested, and I believe it to be also true that specimens were rigorously excluded from these test samples. Also there have been several "mill runs" made on the properties themselves, but personally I believe that every test so made prior to my visit in June was made on special ore and was not representative of the ore as it would be mined under commercial conditions. These mill tests have given results all the way from $8 to $50 in gold per ton, and they are of value in so far as they show that there is some pay rock in the district; but to connect these mill runs with the large ore bodies is misleading.

Though much money has been spent in the district, very little is really known about the extent or value of the pay zones. Four stamp mills have been erected. Two of these, a full-sized 10-stamp mill and a small 3-stamp mill, have been in operation. The other two mills have not yet been completed to the operating stage. Much money has been spent on shafts, tunnels, mine buildings and even gasoline launches, but very little has been expended on surface work on the alleged ore bodies. At one of the properties a responsible official informed me that in one of the shafts on his property, at a depth of two feet from the surface the ore assayed only two dollars, at a depth of ten or twelve feet it assayed $7, while at a depth of 35 feet it assayed $50. If the ore from this shaft would show an average value of $7 per ton, his property would very probably be one of the big mines of the world. If it averaged even $2 a ton, I should consider that the property had a great future. I asked the responsible official of another property why

*From a letter by the writer in the Canadian Mining Journal, Sept. 1st, 1907.

they did not make more effort to determine the value of the ore bodies. He replied that it was little use sampling on the surface; when his shaft was down 100 feet he would cross-cut and sample the ore body then. Now, these were two of the most important properties in the district, and these statements of the officials show the remaining influence of the wild-cat period.

That fiction about the increase of values with depth is one of the most important properties of the wild-catter and boomster. There is absolutely no reason, either from theory or practice, why the ore in the Larder Lake district should carry more gold at 100 feet depth than it does at the surface. As a matter of fact, the richest specimens yet discovered up there have come from the surface, but this is purely accidental. The surface is easily and cheaply prospected; that so little work has been done on it is due either to ignorance or else to the fear of exposing much barren or low-grade ore. The sinking of shafts before the surface has been properly prospected can only be of value for the purposes of selling stock. The same is of course true in an even greater degree in regard to the erection of mills. There is not a property in the district upon which sufficient work has been done to justify the presence of a mill, not even of the small three-stamp, so-called, prospecting mill.

The engineer who makes such statements is locally called a "knocker," and local inhabitants seek to discredit him. In reality the worst knocks the district has had lie in the work that has been done there. Not five per cent. of the money expended has been rationally used for the purpose of finding or exposing pay-ore bodies. The first function of the mills that are being completed at the present time will be to open the eyes of the shareholders to the limitations of the present ore bodies. Their function will be simply to disappoint, so that directors may take a new view of things and begin over again, begin to do what they should have done in the first place, viz., explore.

There are three stages in the proper growth of a mine: exploration, development, production. The present managers at Larder Lake are seeking to attain the last stage without either of the others. And Larder Lake is particularly a district requiring exploration. A large part of the fractured zone with its quartz stringers contains insufficient gold to pay; only here and there in occasional and irregular areas will pay-ore be found. These pay zones must be explored for, and this requires experienced men. It is still a matter of conjecture whether there are any pay zones of sufficient extent to pay for a mill, but probably such zones will ultimately be found. All the local conditions point to the possibility of the existence of some very large bodies of pay ore in this zone of serpentinized dolomite.

To the south and west of the lake discoveries have been made of an entirely different kind of ore. There are some well-defined veins containing massive pyrites, with appreciable quantities of copper. They are reported to contain good gold values. Some systematic exploration work has been done in this neighborhood. Cobalt bloom has been discovered on more than one claim.

Altogether, the district is not without promise, but it is a great pity that it has been so seriously handicapped by wild-cat and ignorant methods of work.

The statement and opinions I have expressed in regard to wild-cats do not apply to the Harris-Maxwell Company. The work done on their property is open to criticism, but their directors have shown a remarkable honesty of purpose.

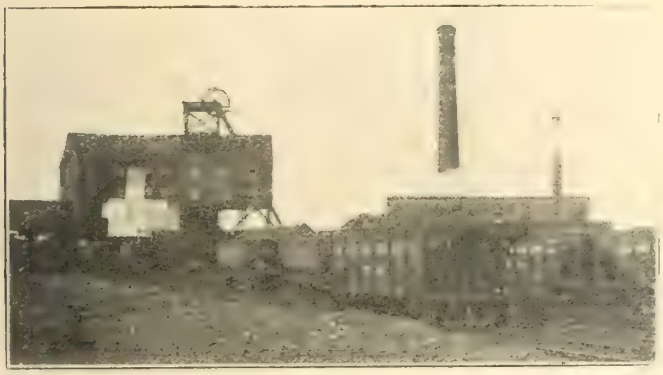
Editor's Note.—We feel justified in appending a note of explanation to Mr. Haultain's article. Mr. Haultain's purpose is to waken a sense of responsibility in the owners and operators of Larder Lake properties. He and other competent judges recognize the fact that, in at least one case, honest work has been done and is being done. The property referred to is being sampled systematically and has a ten-stamp mill ready for operation.

THE MINING OPERATIONS OF THE DOMINION COAL COMPANY.

By F. W. Gray.

(*Continued from last issue.*)

No. 4 Colliery (Caledonia Mines).—Operations were first commenced at Caledonia on the present site in 1866, and shipments date from 1868. The original lessees built a railway along Big Glace Bay Beach, and shipped their product at what was formerly known as Port Caledonia, where they erected an extensive shipping dock, the remains of which are to be seen today half buried in the sand.



Since 1866 Caledonia has produced a little over 8,000,000 tons of coal, of which quantity 6,500,000 tons, or over 80 per cent., has been produced since the Dominion Coal Company took over the mine in 1893. At the present time the output of Caledonia is about 45,000 tons per month on single shift.

The most serious underground accident that has ever occurred in the Glace Bay Basin took place in this colliery. A fire originated in a pump house situated about 1,400 feet to the deep of the pit bottom, in what was known as the Old West deep. A party of men in charge of the underground manager were endeavoring to locate the fire when an explosion took place. From all accounts the explosion was a very slight one, and the 11 men who died were in all probability the victims of carbon monoxide poisoning.

The workings of Caledonia are very extensive, as may be judged from the length of time that the mine has been working. They are divided into two distinct sections by the coal pillar left for the support of Glace Bay Harbor and the creek that flows into it. The west side of the mine is an entirely land area. The east side workings are partly submarine, the most easterly levels being extended at the present time some 2,000 feet from the shore in the direction of No. 6 workings, up to the barrier against which the Caledonia workings will ultimately proceed. The territory between Caledonia east side and the workings of No. 6 Colliery is practically virgin, with the exception of the small area that was extracted from the workings of the Old Clyde pit

The Old Clyde coal mine had the reputation of being of excellent quality.

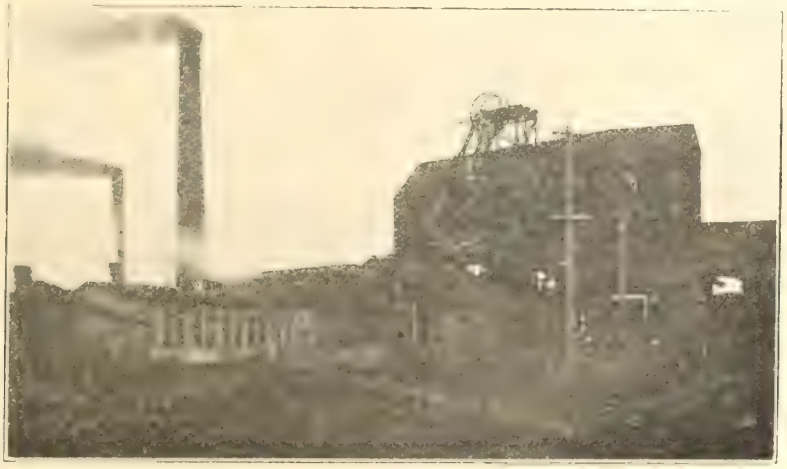
It will be noticed that in the sketch plan of the Glace Bay Basin, that accompanied the first part of Article II of this series, the outcrop of the Phalen seam is shown as a continuous black line across Big Glace Bay Beach, while those of the other seams are dotted. The Phalen outcrop has been proved by boreholes which

Dominion No. 3—Bankhead Approach.

were sunk in 1906, and there is absolutely no dislocation or alteration of the measures between the workings of Caledonia and those of No. 6 mine.

The coal shaft is 185 feet deep, rectangular, and untimbered except for the buntons and spears. It is 18 feet 10 inches by 11 feet, divided into two compartments, one for hoisting coal and the other for the man cage. The cages are of the standard dumping type used by the Dominion Coal Company, and were installed in place of the former platform cages when the plant was taken over. The guides are wooden.

The air shaft is 10 feet in diameter, circular in shape and is divided by a pillar of strata only five feet wide from another shaft of the same dimensions that was sunk side by side and originally intended to be used as a water shaft. At the present time the two shafts are connected at the surface and form in reality one air shaft. The main compressed air column is suspended in the last named shaft. The fan is a Dixon fan of the Guibal type, 14 feet in diameter by 6 feet 4 inches wide, and there is also a spare Murphy fan 12 feet diameter. The ventilating column is depressive, the coal shaft forming the upcast. The air is split at the bottom of the air shaft, one split ventilating the west side, and the other going to the east side where it is again subdivided into two splits. A new air shaft 15 feet by 10 feet finished dimensions inside the timbering and 160 feet deep has just been completed at a point on the shore line distant about one mile to the eastward of the fan shaft. This shaft will act as the upcast for the easterly split of the east side, and will eventually become the main return for the submarine workings of Caledonia.



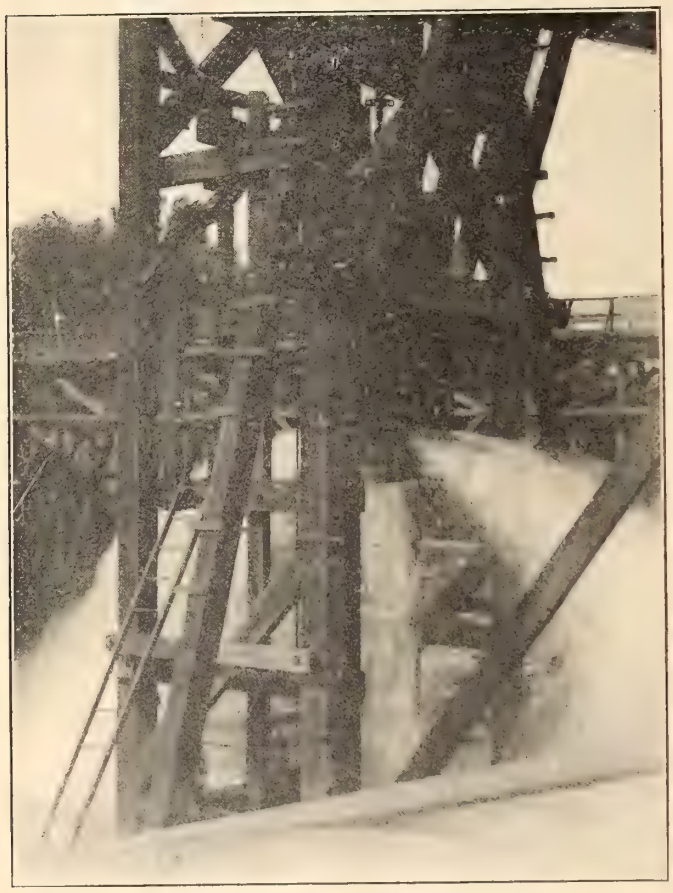
The surface power equipment consists of seven Babcock & Wilcox boilers rated at 1,380 h.p., fitted with Parsons' burners. There is a brick smokestack 125 feet high, and one steel stack 80 feet high.

The coal hoist is the same engine as was originally used at the Gardiner Mines in 1870, and was made by an English firm (Coupe). It is a horizontal engine with 20-inch by 48-inch cylinders, and an 8-foot drum using a hoisting rope 1⅜-inch diameter.

The man hoist was made by Matheson of New Glasgow. It has cylinders 18 inches by 24 inches and a 7-foot drum.

The haulage engine was made by the same people as the coal hoist, being part of the original equipment. It is a horizontal engine, cylinders 22 by 42 and a 15-foot fly wheel. It operates three endless haulages by clutch pulleys on a common shafting, namely the West Level rope, the West Deep rope and the East Deep rope, the length of the hauls being respectively, 6,200 feet, 5,900 feet and 3,500 feet, all using 1⅛-inch wire rope. The usual speed of the haulage is 1.75 miles per hour.

The compressor house is a concrete building and contains one American Rand compressor installed in 1897, steam cylinders 40 inches by 32 inches, air cylinders 36 inches by 22 inches, 48-inch stroke, 60 revolutions with a capacity of 3,200 cubic feet per minute; one Rand compressor steam 36 inches by 20 inches, air 32 inches by 20 inches, 48-inch stroke, 60 revolutions capacity 2,500 cubic feet per minute. There is also a small Ingersoll straight line compressor of 900 cubic feet capacity. An automatic lubricating system is to be installed, but is not yet in place.



Dominion No. 4 (Caledonia)—Looking South.

The colliery surface and pit bottom are lighted by current obtained from the Central Electric Plant and transformed at the colliery.

The amount of mine water that has to be dealt with at Caledonia is greater than at any other collieries on the Phalen seam, as it deals not only with its own

water but with that of No. 3 Colliery to the westward. The water shaft, situated on the side of Caledonia Brook a short distance below the colliery, is capable of dealing with large quantities of water. The shaft, which was sunk in 1900 for the purpose of unwatering the mine after the fire, is 266 feet deep and is fitted with tanks having a capacity of 800 gallons each. These tanks are of the usual type with side outlets for the water. Side discharge tanks were formerly used here, but they have been discarded in favor of the present design as they are less wearing on the guides and generally more suitable. The hoist is a horizontal engine, cylinders 20 inches by 42 inches (Whiting & Shaw). The greatest capacity of the hoist is three tanks per minute, and it has lifted as much as 67,000,000 gallons of water in one month.

Caledonia Water Shaft.

The underground pumps have up to the present time been driven by compresed air, but is unnecessary to describe these as they are being replaced by an entirely new set of electrically operated pumps. On the west side there is a five plunger Aldrich pump with a capacity of 600 gallons per minute, and a twelve stage Gwynne centrifugal pump, driven by 150 h.p. Westinghouse motors. The pump house is built of brick with walls one foot thick, having projecting buttresses every six feet. The roof is supported by 20-inch steel girders. The floor is concrete and the whole construction is as nearly fireproof as can be made. The transmission lines are caried down a borehole situated on Chapel Hill at Glace Bay, and the discharge will be made through a contiguous borehole 590 feet deep.

The East Side boreholes are situated at Quarry Point and are about 440 feet deep. The pump house underground is of similar construction to that on the west side. The pumps are two 3-stage McDougall turbines driven by two 100 h.p. Westinghouse motors, and rated at 420 gallons per minute against a 450-foot head.

The discharge boreholes are 10 inches finished diameter inside the cast iron casing which is filled in with concrete. The transmission boreholes are not cased and are 6-inch diameter.

The current is transformed on the surface, the transformers house being situated near to the boreholes.

The surface erections comprise a machine shop, lamp cabin, warehouse, etc. The bankhead is a steel structure housed with corrugated iron and fitted with the usual screening arangements and picking belts. The wash house has recently been fitted with a sprinkler shower bath, an innovation which is being readily taken advantage of. Shower baths are the accepted and best method of cleansing for the use of miners after their work, as they are clean and sanitary, are economical in the use of water, and cleanse very effectively by reason of the mechanical effect of the falling water. They are much preferable to slipper baths which speedily foul unless kept with the most scrupulous care.

The firemen's hall, which Caledonia has, in common with the other mines, is shortly to have a shower bath and its compliment of Draeger apparatus.

The mine is fully equipped with A. & B. safety lamps, and fire fighting appliances. About 650 men are usually employed. The mine has in the neighborhood of 80 horses.

The population of Caledonia is composed mostly of life long residents, largely of Scotch Highland descent. The community boasts of a band o pipers who wear the garb of Old Gaul, and the "boys" of Caledonia have a Gaelic yell, which they use on befitting occasions, that would do honor to any McDonald that ever struck terror to the heart of the Sassenach with his slogan.

(to be continued.)

ACT ACCOMPLISHES GOOD.

Disputes Legislation Prevents Twenty-Eight Strikes.

Washington, July 18.—That the Canadian industrial disputes investigation act for the prevention of strikes affecting public utilities has accomplished the main purpose for which it was enacted is the conclusion drawn after a special investigation of the workings of the law by Dr. Victor S. Clark for the Bureau of Labor in a report made public to-day. From March 22, 1907, when the act went into effect, to January 15th, 1908, thirty disputes became subject to investigation and in twenty-eight cases strikes were averted or ended. The law prohibits a cessation of industry, under penalties, until by the investigation of an official board the public is officially informed of the grounds of the controversy, reliance being placed upon public opinion to prevent or shorten such disturbances.

The law provides for boards of conciliation and investigation. Dr. Clark reports that no employer was found who was not favorable to the law, as better than no legislation, as far as it applied to railroads, and that there is some sentiment in its favor among the rank

and file of the workers, though some representative labor leaders are opposed to it.

Among the public most of those who are practically familiar with labor matters approve the act. Its effect has been to cause the public to take an interest in many industral disputes quite as immediate and important as that of the conflicting parties. Apparently the law has not affected adversely the condition of workingmen or of industries where applied.

DEISTER SLIMER AND SUSPENDED TYPE VANNER TESTS AT COMBINATION MILL OF GOLDFIELD CONSOLIDATED MINES COMPANY.

	Average of All Tests.	
	Deister.	Suspended Type.
Total solids in feed per run in tons....	33.75	39.4
Total solids in 24 hours, in tons..	8.90	10.006
Value of feed per ton in ounces	.97	.97
Total value of feed in ounces..	32.736	39.40
Value of concentrates per ton in ounces	14.27	17,20
Per cent. of extraction by product....	41.89	32.51
Per cent. of extraction by assay of heads and tails..	40.10	35.85
Flow to callow tank in pounds per min.	137.7	
Dry solids in pounds per min.	16.36	
Water in pounds per min.	115.5	
Overflow of clear water in per cent...	48.15	
Per cent. of solids in discharge..	22.62	

The above table gives a record of the performance of the Deister, in competition with a suspended vanner. The tests were conducted during May and June of this year, at the Combination Mill of the Goldfield Consolidated Mines Company. As a direct result of the competition seventy No. 3 slime tables were ordered at once.

The new miners' lamp of Santa and Spelmans, of Brussels, is designed to give warning of danger, and is based on the principle that a flame like that of benzine remains constant in size and brightness under constant conditions, but is increased by such a gas as fire-damp and reduced by carbonic acid. The lamp has a protective casing of wire-gauze provided with external cooling ribs. It is surmounted by a refractory chimney, through the opposite sides of which pass the elements of a thermopile, and any variation of current is shown by a galvanometer in connection with these elements. If the flame is made larger and hotter by the presence of fire-damp, the thermo elements are affected, an increase of current intensity being indicated by the galvanometer needle. Carbonic acid gas, reducing the flame, is similarly signaled by a reduction on the galvanometer scale, and a recording apparatus connected with the galvanometer may be made to keep a record of the varying conditions in different parts of the mine's workings.

The idea of using house refuse for fuel, as is being so successfully attempted in the refuse-burning plants of large cities, is supplied on a small scale in the new fuel —called "coalescine"—of an English borough engineer. Garbage, bits of unburned coal from the ashes, and other waste, are pulverized, mixed with tar, and made into briquettes. This fuel is claimed to be not only perfectly hygienic, but to show high efficiency under boilers. The cost is so moderate that small towns are enabled to dispose of their waste by a practically self-supporting method.

A redistribution of the chemical elements—especially of the metals—has been going on through the agency of man for some thousands of years, and Mr. H. M. Atkinson, a British chemist, points out that the total effect must be considerable. The gold and other metals concentrated in small spots near the surface of the older rocks are being rapidly mined and put to use, the fine particles from their weir being carried down streams and eventually diffused through the deposits at the mouths of the rivers. Tin oxide, for example, is mined at a few places, spread out pretty uniformly over the earth, and in the refuse of towns the waste tin is oxidized, carried away by water, and on the sea bottom the fine particles are so scattered as to be beyond future recovery by any process known. The effect may be modified to some extent by the concentration of metals in solution and other causes. As the common receptacle of all waste, the sea must be slowly changing its composition from industrial processes—notably from soluble chlorides and other factory waste and from the salts of potash and lime that are taken from mines, and used on the soil by farmers.

Selenium, discovered by Berzelius in 1818, is a non-metallic element closely related to sulphur and tellurium. In darkness it is practically a non-conductor of electricity, but when lighted it passes current readily, and it is this unique variability that gives to the substance great possibilities of future importance. The curious property has been applied experimentally in various ways. It has given a means of transmitting speech along a ray of light, a method of guiding and exploding torpedoes by light, and it is employed for sending pictures by wire. It has been used also for measuring the Roentgen rays applied in medicine. Selenium, now selling at 50 cents to $2.00 per ounce, is a rare substance in little demand, but in the United States it has been produced experimentally from the anode slimes of the electrolytic refining of copper, and it is probable that a moderate supply can be obtained in this way.

In his new iron-making process, Dr. G. P. Layal, of Stockholm, finely pulverizes the ore, coal and other materials, and causes them to be drawn by a current of air or carbonic oxide in a continuous stream from the hopper through a delivery pipe into the furnace. The furnace is a vertical cylinder, with a tap hole for the iron and an escape hole for the gas near the base. The coal is burned to carbonic oxide in the upper part of the furnace, and the slag and reduced iron collect on the furnace wall and flow down to the lower end.

In a new French Welsbach mantle, the rare oxides are consolidated in an electric furnace, greatly increasing resistance to shocks, tremors and draughts.

THE TREATMENT OF STAMP MILL TAILINGS AT THE RICHARDSON MINE, GOLDBORO, N.S.

By E. Percy Brown, S. B.

The treatment of the tailings from the mine of the Boston Richardson Mining Company having been attempted in various ways, it may be interesting and instructive to outline the various steps and note the results obtained by the different methods.

For a general description of the mine and the characteristics of the ore, the reader is referred to an article in the "Canadian Mining Journal," June 15, 1907.

The first treatment of the tailings, outside of laboratory work, so far as the writer is aware, was at the Chlorination Plant of the Brookfield Mining Company, Queens County, N. S., carried out by the writer in July, 1897.

About one ton of concentrates, worth $18 per ton, was treated by roasting and chlorination, giving an actual extraction of 89 per cent. of the value in the roasted ore. The loss of gold in roasting was high and was probably due chiefly to the fact that it was impossible to avoid a loss of ore in handling so small a lot through the large furnace.

In consequence of the success of the treatment a shipment of one hundred tons or more of concentrates was made to the chlorination plant at Brookfield two or three years later.

It is understod that this treatment was not successful, probably due to the fact that the concentrates were old and had become oxidized and caked, so that thorough roasting was impossible.

The cost of roasting and chlorinating such ore in Nova Scotia was from $5 to $6 per ton with an expensive plant.

The next step was the erection of a very large cyanide plant at the Richardson mine to treat the mill tailings direct without concentration. While the percentage of recovery was satisfactory and no difficulty was met in treating the tailings in this way, the values were too low to admit of profitable recovery, being about one dollar per ton.

Early in 1905 Mr. H. S. Badger, assisted by the writer, superintended the installation of a Wilfley concentrator and made a trial treatment of the arsenopyrite concentrates by bromo-cyanide. These tests were so successful that five more Wilfleys were installed and the small cyanide plant, shown in the accompanying sketch was erected.

This process has been successfully used ever since and beyond a few difficulties easily overcome by experimental work has given no trouble.

The method of treatment used is based on the regular Sulman-Teed process with the exception that ordinary zinx box precipitation is used, giving entire satisfaction. In the clean-up the zinc box residues are treated with sulphuric acid, washed by decantation, dried on filter paper in large funnels and carefully roasted. The roasted slimes are then melted in a large graphite crucible with borax glass as a flux, giving a clean brick of gold. The sketch of the plant is self-explanatory. The shaking sluice (K) runs along the ends of the Wilfley tables and conveys the concentrates into the sump (H).

As no fall is available the concentrates must be lifted to the level of the treatment tanks.

A carrier (F) is used and is of such a pattern that the ore must be shovelled into the vats. This ensures an even distribution over the tank.

The method of handling may seem awkward, but the one man necessarily employed at this portion of the work has ample time to attend to his duties.

The following table gives in concise form the results for the year 1907:

Month 1907	No. Tons	Average Value Stock Per Ton	Total Value of Stock	Average Value Tails Per Ton	Total Value of Tails	ESTIMATED: Average Extraction Per Ton	ESTIMATED: Total Extraction	ESTIMATED: Per Cent	ACTUAL: Weight of Bullion	ACTUAL: Value Per Ounce	ACTUAL: Total Value	ACTUAL: Per Cent	LABOR: Total	LABOR: Per Ton	CYANIDE CHARGES: Total	CYANIDE CHARGES: Per Ton

The percentage of recovery, as given above may seem low, but it must be noted that the costs are also low, and while the percentage of recovery might be increased by further treatment, it has been considered that this would not cover the increased cost.

The tailings from the cyanide treatment, which contain 40 to 50 per cent. of gangue (necessary for successful percolation) are now being reconcentrated and shipped to Germany. After this reconcentration they contain 39 to 40 per cent. arsenic and command a good price for this arsenic, and gold contents.

Experimental work, particularly some carried out by students of the Massachusett's Institute of Technology, indicate that the future method of treatment will be a combination of roasting for the recovery of the arsenic and bromo-cyanide for the extraction of the gold. Probably this work will be somewhat along the lines of the method used with such good results at Deloro, Ont.

It can be seen by a glance at the sketch of this plant that the construction is simple in the extreme.

The total cost of erecting such a plant would be about $1,000, exclusive of grading or boiler power.

The four tanks are capable of treating all the concentrates in the tailings from the 60 stamps, this ore carrying from two to three per cent of concentrates.

It is hoped that other gold mining companies in Nova Scotia may be induced to adopt some similar measures to save the gold now being lost in the tailings from their stamp mills.

| COST | | |

THE ORIGIN OF BOMBSHELL ORE.

BY H. M. CHANCE.

The term "bombshell" ore is applied by miners and iron-masters to hollow masses of limonite—brown hematite—which sometimes are round or oval, but more commonly are of any irregular shape. The "bombs" may contain water, clay, sand, quartz, flint, pyrite, siderite, sandstone or decomposed slate, or may be entirely empty. Geologists usually speak of such ore as nodular or concretionary. A careful examination of the literature of ore deposits, and especially of that relating to the genesis of limonite ores, fails to disclose a satisfactory explanation of its origin or mode of formation. By many it is assumed to be similar in origin to silicious geodes, which are supposed to be formed by the deposition of silica or silicates upon the walls of cavities, while others describe it as of "concretionary" origin without attempting to explain the process of formation or the manner in which it has occluded the variety of materials which are found in the interior of different specimens from the same locality. That it is not of concretionary origin is evident upon even cursory consideration, for concretions are masses of material arranged in concentric layers around a central nucleus. The latter may be a grain of sand, a pebble, fossil, or any substance around which (as a core) the concretion forms, growing from the center by the successive addition of concentric rings. Concretions are perhaps merely symmetrical segregations.

The peculiarities of this ore are well described by Professor T. C. Hopkins, *Bull. Geol. Soc. Am.*, 1890, Vol. II., p. 477, etc., as follows:

"Nodular ore consists of irregularly rounded masses, varying in size from a fraction of a pound to several hundred pounds in weight. The masses are frequently hollow, but some enclose a rounded or sub-angular rock fragment, which is sometimes sandstone, . . . sometimes chert, sometimes slate, and sometimes clay. Some shells are filled with clay and sand, and workmen report finding many of them filled with water. Some are filled with clay, which still retains the laminated structure and appearance of the original slate from which the clay was derived; furthermore, the slatey structure was found to extend through the ore shell, which showed, besides the plain lamination of slate, a faint concentric structure as well. . . . While only one shell was found still retaining the laminations of the clay, there were many others containing clay and sand. Some of the shells were but thin crusts, while others were quite thick, almost solid; some have a smooth, velvety or bright mammillated inner surface, frequently coated with manganese oxide. In some instances the lining of the shell is covered with many small stalactites of ore. . . . Many of the shells are lined with a dense fibrous layer, often an inch or more in thickness. . . . The thinner shells have all been broken, and we see only the fragments of them in the clay-ore masses. This shell form of ore . . . forms an appreciable part of the ore body in many cases. The small, irregular, nodular-like pieces of ore, commonly known as shot ore, are presumably closely related in origin to the shells. . . ."

The inner wall of many bombs consists of a hard, bright brown or jet-black glazed surface, carved, rounded or botryoidal. This is frequently described as a manganese coating, but is doubtless a film of iron or manganese silicate. Occasionally the interior or a part of the interior is lined with a layer of extremely hard, flinty, liver-colored iron silicate, or with quartz crystals or chalcedony, and the same silicate frequently forms a considerable portion of the body of the shell or of its outer layers, but generally the shell is composed of high-grade limonite, of a fibrous structure, especially in those layers forming the inner lining of the shell.

These peculiarities are satisfactorily accounted for neither by the theory that these ore masses owe their origin to concretionary action, nor by that which assumes the direct deposition of ferric hydrate upon the interior of rock (limestone?) cavities. They may, however, be explained by assuming that the bombs are the residual masses, remaining after oxidation, of iron sulphides or carbonates containing sand or clay or both in varying proportions.

If the material from which this ore is formed consists of sandstone, or of sandy slate, or of clay slate, impregnated more or less completely with pyrite or siderite, the formation of bombshells, containing just such materials as are found in these shells, may be readily explained, especially if the iron impregnation be in the form of pyrite or marcasite, that is, FeS_2.

If such sandstone or slate is broken and fissured by faulting and crushing, and by the development of cleavage planes, oxidation by percolating waters will proceed along the joints or planes which form the channels through which these waters circulate, and in each fragment of the mineralized rock oxidation will commence upon the outside and progress towards the center.

In this way an outer skin or shell of limonite first forms on the outside of the fragment, for if the iron be present as pyrite or marcasite, while some of it may be removed as ferrous sulphate, this salt, if formed, may immediately be oxidized and precipitated *in situ* as ferric hydrate. The sulphuric acid formed by the oxidation of the remaining molecule of sulphur will attack and decompose the clay of the gangue, removing the bases as sulphates in solution; the silicic acid also escaping in solution, or combining with iron oxides to form iron silicates, remains as an integral part of the ore.

If clay be present in large quantity a portion will remain undecomposed in the center of the bomb, together with all of the sand originally present in the gangue.

Hence, if the original pyritic material has a clayey (slate) gangue, bombs may form containing no residual matter, or containing more or less clay; if the gangue be sand and clay (arenaceous slate), the sand only, or sand and clay may remain; if the gangue be sand only, some of this will remin as an impurity in the limonite forming the body of the shell, and some as a partial filling of the interior of the bomb.

It is now well known that pyrite (or marcasite) oxidizing underground, whether by waters carrying free oxygen, or by waters containing no uncombined oxygen, or by reactions involving hydrolysis, does not behave in the same way as when oxidized by exposure to the air above ground. One of the most common reactions above ground is that in which sulphur is set free, often written:

$$FeS_2 + 4O = FeSO_4 + S.$$

but this rarely occurs beneath the surface, for the gossans of pyritic veins seldom carry free sulphur, although there are a few noted examples in which large deposits of sulphur are found between the surface and the unoxidized portions of such veins.

In the absence of oxygen, carbonates in solution may, as shown by Dr. N. H. Stokes, completely oxidize the iron of pyrite or marcasite thus:

$$8FeS_2+15Na_2CO_3=4Fe_2O_3+14Na_2S+Na_2S_2O_3+15CO_2,$$

and under proper conditions of temperature and pressure the ferric oxide thus formed may be deposited as hydrate; but these reactions do not satisfy the observed conditions, and it seems more probable that oxidation near the surface has proceeded as indicated by some of the following reactions:

$$FeS_2+H_2O+7O=FeSO_4+H_2SO_4;$$
$$3FeS_2+8H_2O+22O=Fe_2O_3,\ 3H_2O+FeSO_4+5H_2SO_4;$$
$$2FeSO_4+5H_2O+O=Fe_2O_3,\ 3H_2O+2H_2SO_4;$$
$$2FeS_2+7H_2O+15O=Fe_2O_3,\ 3H_2O+4H_2SO_4;$$
$$2FeS_2+4H_2O+15O=Fe_2O_3+OH_2SO_4;$$
$$2FeSO_4+2H_2O+O=Fe_2O_3+2H_2SO_4;$$
$$6FeSO_4+3O=Fe_2O_3+2Fe_2(SO_4)_3;$$
$$6FeSO_4+3H_2O+3O=Fe_2O_3,\ 3H_2O+2Fe_2(SO_4)_3;$$
$$2Fe_2(SO_4)_3+2FeS_2+4H_2O+12O=6FeSO_4+4H_2SO_4.$$

The sulphuric acid having been formed in direct contact with the gangue, it is reasonable to suppose that it must at once attack any clay or other decomposable material, and the removal of the soluble silicates and silicic acid by transfusion through the walls of the bomb is readily pictured. It is, however, possible that the colloidal silicic acid may be retained, and further, that it may perhaps often be set free in a gelatinous condition. This latter hypothesis may account for the frequent presence in such ores of a skeleton of amorphous silica which appears to completely ramify some parts of the limonite.

If the oxidation proceed according to these equations, the successive additions of layers of limonite to the interior of the shells is doubtless due to the further oxidation of the ferrous sulphate as above shown, the oxidation of the solution occurring at or in the wall of the shell where the solutions, in escaping by transfusion through the walls of the shell, are met by oxidizing waters transfusing towards the center of the shell. Under such conditions the ferric hydrate would be deposited in the pores of the shell or upon its inner surface.

In attempting to picture these reactions and their results, it is important to remember the extremely slow rate at which oxidation proceeds under such conditions. Even at the surface, where decomposition is comparatively rapid, the oxidation of pyrite appears to progress at a very slow rate, perhaps not exceeding an inch or a few inches in depth in several hundred years.

If the iron be present as carbonate, a precisely similar series of reactions may be conceived, in which carbonic acid transposes the silicates, freeing silicic acid and removing the bases as soluble carbonates.

Other observers have noted the occasional presence of a central core of siderite or pyrite in bombshell ore, but have generally attributed the presence of such cores to concretionary action and replacement by sulphates (accompanied by reduction to sulphide) or carbonates in solution.

The foregoing theory, advanced to account for the origin of bombshell ore, is based upon a study of these deposits dating back to 1885—when the writer was personally engaged in mining brown hematite ore—and upon examinations of many specimens which show more or less clearly the character of the original material from which such ore is formed. It will form an integral part of a broader statement, extending the application of this theory to the genesis of limonite ores, and including a discussion of the original sources of the iron, methods of mineralization, and subsequent decomposition and precipitation.

EXCHANGES.

The Engineering and Mining Journal, July 25, 1908.—James Ralph Finlay contributes to this number an article on the "Cost of Producing the World's Supply of Copper."

At the Wallaroo and Moonta mines of South Australia the present cost of mining, concentrating and smelting a ton of concentrates is about $35 per ton. The vein matter of each mine contains from 3 to 4 per cent. copper, the concentrates from 11 to 20 per cent. The veins are fissure veins in metamorphic schist and prophyry.

The only important copper mine in the United States east of Lake Superior is that owned by the Tennessee Copper Company, where large leases of copper-bearing pyrites are worked. Fuel and transportation are cheap, but all the ore has to be smelted. The ore yields only 32½ pounds copper per ton. The current operating costs for 1907 were:

Mining	$1.22
Smelting	2.14
Administration	0.49
Total	$3.85

To this should be added, according to Mr. Finlay, 21 cents per ton for the use of the mining plant, and 47 cents per ton for the use of the railroad and the smelting plant. These items bring the total up to $4.53. On this basis anything received above 12 cents per pound for copper in New York is applicable to dividends and anything above 14 cents is net profit after allowing for return with interest of money invested in the plant. These costs are from 5 to 10 per cent. higher than the average.

The Utah Consolidated Company mines and smelts ore averaging by actual recovery, 60 pounds copper, 1.33 ounce silver, and 0.104 ounce gold per ton. The total metallic extraction is equal to 80 pounds copper at 14 cents. The total cost per ton is $5.88 per ton of ore. Everything above 6.75 cents per pound for copper goes to stockholders as dividends.

At Mount Lyell, Tasmania, the total cost per ton of ore is $5.52.

At the Granby Consolidated, British Columbia, the corresponding figure is $5.75.

The article concludes with some valuable general considerations, including comparisons of disseminated

ores, quartz-pyrite ores, and ores that must be smelted in bulk.

The Mining World, August 1, 1908.—"Some Striking Features of Rand Gold Production" is the title of an article by Ralph Stokes.

From the year 1887 up to the end of June, 1908, the Transvaal has produced gold to the value of $1,000,000,000. Despite labor troubles the production of the Transvaal is increasing steadily. Before the war the maximum annual production was $80,000,000. The yield for the first six months of 1908 exceeds $68,000,000 for the Rand only. This, Mr. Stokes remarks, is the more striking in the light of the gradual diminution of the ore's grade.

Kaffir labor is replacing Chinese. The exorbitant wages of white miners are being reduced. So also are contract rates. Everywhere "cost sheets" are revealing the results of stringent economy. The Robinson Company, under American management and ununder the control of Messrs. Wernher, Beit and Eckstein, is quoted as an outstanding example of the benefits of rigid reduction of costs. Here the total working costs have been carried down to $3 per ton. The attainment of this figure throws an enormous body of ore, formerly unprofitable, into the category of payable ore.

Since January, 1888, the Robinson has paid $29,939,000 in dividends.

The Colliery Guardian, July 24, 1908.—A special contributor discusses in this issue the efforts made by British workmen to obtain compensation under the Workmen's Compensation Acts in respects of injuries caused by the acts of fellow workmen during the employment, but which have no relation to that employment. Several instances are cited where workmen were injured through practical jokes. In one case a workman was hoisted fifty feet in the air by means of the hook of a crane passed through his necktie. The man fell to the ground and was crippled for life. In this and similar cases attempts to establish the liability of employers have failed.

The Iron and Coal Trades Review, July 24, 1908.—The increasing use of mechanical coal cutters in British collieries is the subject of editorial notice in this number of the Review. In 1906 only 1,133 machines were at work. During the year 1907 the number added was 360, making a total of 1,493. This is by far the largest number added in any one year.

However, out of Great Britain's total output of 267,828,000 tons of coal, only 12,877,000 tons were cut by machine. Hence the movement has yet far to go.

Compressed air is more largely employed as motive power than is electricity. The average quantity of coal cut per machine in 1907 was 8,625 tons, as compared with 9,004 tons in 1906.

Electrolysis of pipes is now prevented by insulating from the ground. The pipes are covered with a specially-prepared asbestos paper, coated with a waterproof insulating compound, and joints are made tight by strips and insulating cement. The protection is claimed to be permanently durable.

PERSONAL AND GENERAL.

Mr. John E. Hardman recently reported upon several copper deposits on the north shore of Georgian Bay.

Mr. Fraser Reid, superintendent of the Coniagas concentrator, has returned to Cobalt after a brief honeymoon.

Mr. Hiram W. Hixon, late general manager of the Rand Nickel Company, is spending the summer at Fairbanks Lake, near Sudbury.

Mr. J. B. Tyrrell, the well known Toronto mining engineer, left on August 13th for Saskatchewan. Mr. Tyrrell will return about September 1st.

Mr. W. F. C. Parsons, mining engineer to the Londonderry Iron and Mining Company, Londonderry, N. S., is examining the Bathurst, N.B., deposits for the Drummond interests. Mr. Parsons will also make a professional visit to Mayo, Ont.

Mr. Alexander H. Smith, general manager of Los Reyes Gold Mining and Milling Company, Oaxaca, Mexico, is in Toronto. Mr. Smith has recently visited the copper mines of the Lake Superior region. He is returning shortly to Mexico.

Dr. Henry Youle Hind, who died at Windsor, Nova Scotia, on August 9th, was the author of the following publications: "Prize Essay on Insects and Diseases Injurious to the Wheat Crops," 1857; "Narrative of the Canadian Red River Exploring Expedition of 1857, and of the Assiniboine and Saskatchewan Exploring Expedition of 1858," 1860; "Explorations into the Interior of Labrador Peninsula," 1863; "Eighty Years' Progress of North America"; "Notes on the Northern Labrador Fishing Ground," 1876; "The Effect of the Fishery Clauses of the Treaty of Washington on the Fisheries and Fishermen of British North America," 1877; "Sketch of the Old Parish Burying Ground, Windsor, N.S.," 1889; "History of the University of King's College, Windsor, N.S.," 1890. The degree of M. A. was conferred on him by Trinity University in 1853; and the degree of D. C. L. was granted to him by King's College, Windsor, of which college he was for many years a Governor, in 1890.

CORRESPONDENCE.

To the Editor

"Canadian Mining Journal."

Dear Sir.—

The clipping* which I send you doubtless refers to the special representative's work who was sent to Canada by our president. I will be indebted to you for an outline of your Canadian Act on the subject of compulsory arbitration. Please give same in your Journal.

I have had considerable experience with labor, especially with coal miners, and have had charge of mines in various parts of the United States and Canada. Some of the middle western coal mining States, e. g., Illinois and Indiana, formerly had State Boards of Arbitration. The services of these Boards were merely conciliatory, and neither party to the controversy was required to abide by their decision. Yet these Boards rendered good service. I do not believe compulsory

* See page 398.

arbitration would be of service in the States, even if it could be made constitutional.

In your columns I note frequently reference to labor troubles among coal miners. Recently I read of a strike at Michel resulting from the refusal of a superintendent to employ an objectional miner. This cause rarely leads to troubles over here as the unions (I refer to the U. M. W. of A. more particularly) generally recognize the superintendent's right to employ or to refuse to employ any man. From my observations in Cobalt I rather doubt the efficiency of your law on compulsory arbitration.

Kindly give an outline of your law and comments on the same in your journal.

Very truly yours,

American Coal Mine Manager.

[Editor's Note.—This is the clipping referred to by our correspondent. We shall publish some comments on the Industrial Disputes Act in an early number.]

Editor Canadian Mining Journal, Toronto, Ont.:

Dear Sir,—Will you please insert the following correction: In several newspapers last week, and now in the Engineering and Mining Journal, there is a statement concerning placer gold in the Larder Lake district. "Professor Willmott" is quoted as the authority. I wish to state that so far as I am concerned I have never been at Larder Lake and made no report to anyone on placer gold in that region. Yours truly,

A. B. WILLMOTT.

Sault Ste. Marie, Ont., August 11, 1908.

INDUSTRIAL SECTION.

Bulletin No. 16, The Jeffery A-5 Electric Rotary Drill.—This machine is designed on essentially new lines for heavier work than it is usual to attempt with electric rotary drills. For drilling coal, slate, rock salt, clay, gypsum and other soft material it possesses distinctive features. The motor, entirely enclosed in a damp and flame-proof casing, furnishes ample power. Changes in speeds and rates of feed are quickly and easily effected. A friction release checks the forward movement in case excessive resistance is encountered and makes possible the drilling of harder material than is practicable with a positive feed. The drill is easily handled and set in position. Special auger bits are provided.

Jeffrey Bulletin, No. 25.—Handling Coal and Ores.—A well illustrated catalogue showing engravings and sections of steel tipples, roller shaking screens and loading chutes.

Compressed Air Appliances and Uses of Compressed Air.—Canadian Rand Company, Limited, Montreal.—The Canadian Rand Company has designed air power machinery for the past twenty years. The pamphlet before us embodies in crisp form the results of the company's experience in designing and manufacturing compressed air appliances. In the machine shop, in the foundry, in the boiler shop, in structural steel work, the uses of compressed air are too numerous to mention. The air-lift system of pumping artesian wells by means of compressed air is superseding the old deep well pump. In many industries, such as tanning, stone work, etc., modern conditions demand its use. For house cleaning, car cleaning, etc., compressed air is now considered indispensable.

This recently issued catalogue presents illustrated descriptions of air hoist valves, air hoists, Rand trolleys, Rand jib cranes, compressed air elevators, hydropneumatic elevators, compressed air jacks, pneumatic rams, broaching hammers, blacksmiths' air hammers, "Imperial" pneumatic tools, "Imperial" motor hoists, jaw riveters, injector sand blast, air compressors and Rand rock drills.

The "New Slugger" rock drill marks a departure in design. The valve is of the piston variety with a movement of only a fraction of an inch. It strikes an uncushioned blow and operates with a variable stroke. By cranking the drill up close to the rock, or back from the rock, the stroke may be varied from one-half inch up to the full stroke of the machine. This variable stroke is of special advantage when spotting a hole in a glancing place, or to enable the drill to free itself in close quarters, or in case the steel is a little too long.

The Rand Class "C" portable self-contained air compressor is worthy of especial note. It is designed for prospecting, mining or general operations on undeveloped or difficultly accessible properties where a large outlay of money is not warranted.

Bulletin No. 40 "Cleveland" Stope Drills.—The Cleveland Pneumatic Tool Company, Cleveland, Ohio.—The first inside page of this bulletin is noteworthy. On it is printed a half-tone of a well known mine-manager of Cobalt operating a "Cleveland" No. 40 hammer drill.

The pamphlet, alluding to the small amount of power necessary to run the No. 40 hammer drills, points out that a gasoline engine and small compressor, capable of supplying power to one 2¾-inch reciprocating drill, will run two or three No. 40's.

SPECIAL CORRESPONDENCE

NOVA SCOTIA.

Glace Bay (August 3).

Output of the Dominion Coal Company's mines for July, 1908:

No. 1	51,782
No. 2	66,845
No. 3	39,507
No. 4	41,936
No. 5	49,827
No. 6	24,073
No. 7	17,435
No. 8	23,646
No. 9	29,871
No. 10	19,751
	364,673

After a great deal of hard work and patient investigation the arbitrators appointed to act on the Board on Conciliation between the employees of the Nova Scotia Steel Company and that company have arranged a satisfactory settlement between the parties to the dispute. The following statement, which was officially issued to the press, will explain the nature of the settlement:

On Saturday a settlement was reached in the matter of the dispute between the Nova Scotia Steel and Coal Company and its employees in the colliery department.

Much evidence was taken on behalf of the men, and the company, and the matters at issue were discussed in all their bearings. Every opportunity was afforded the parties of reaching a mutually satisfactory agreement. In the end the Board of Conciliation formulated a basis of settlement which involved an adjustment of rates as between the higher and lower scales of remuneration, though a great difference would still remain. This adjustment involved a moderate reduction on some of the higher paid work in No. 3 colliery, and an increase in the wages paid to certain grades of lay labor through the collieries, and also an increase in pay for the less remunerative mining in No. 1 colliery. The increase in wages is considerably more than the decrease and the difference is supplied by the company.

The award of the board was referred to the various lodges on Friday evening, and on Saturday morning the sub-council of the P. W. A. met at the town hall of Sydney Mines to receive the reports of the delegates from the lodges and to take final action on the award of the Board. It is understood that the representatives of No. 3 mine were opposed to the reduction of their scale of rates, but by a large majority, the sub-council voted to accept the award of the Board.

The company having also agreed to the award it was signed by the representatives of both parties. Mr. T. J. Brown signing on behalf of the company, and Messrs. Moffatt, Galagher, McLachlan and Dorsay on behalf of the men, while Prof. Shortt and J. W. Maddin also signed as members of the Board of Conciliation.

By the terms of the agreement the previous rates in No. 3 are reduced as follows: For machine men, one-half cent per ton; for shot-firers, one cent per ton, and for narrow works, five cents per ton. These reductions will amount to $550 per month, to which the company agree to add $300 per month. The total of $850 per month, or $10,200 per annum, will be devoted first to increasing the wages of day laborers from $1.38 to $1.45. Second to increasing the scale of payment for falling stone in No. 1 mine. The new rates take effect from August 1st.

It will be seen that the settlement has been come to along similar lines to that arranged under the same chairmanship between the workmen and the management of the Dominion Coal Company in March of this year, namely, an increase to the low paid men and a slight reduction in the wages of some admittedly highly paid workmen. This same extraordinary gap between the wages of men working side by side has for many years operated very disadvantageously on the labor situation in the Cape Breton collieries. The Conciliation Boards are doing very good work in Nova Scotia. Where the matters in dispute are of serious moment, affecting large numbers of men and communities the method of conciliation afforded by the working of the Lemieux Act is proving to be a very beneficent one, but where the matters are trivial it can easily be seen that the constant appointment of such boards will prove a vexatious proceeding, if carried to unreasonable limits. If the law is administered with sound judgment, limiting its application strictly to cases where its operation is necessary, we shall have the working basis of arbitrational legislation applied to labor and wages disputes that will make Canada a land of freedom from strikes. If this can be achieved we shall have gained a point in the industrial game which will considerably advantage us against our southern neighbors. We rather think that the submission of the men's case by a native labor union before a tribunal impartially constituted under a Canadian law has resulted in better things than would have resulted from the efforts of a foreign labor organization, deprived of that subtle force of public sympathy whose effect it is hard to estimate. Public opinion is something that no corporation, however arrogant, and no labor union, however aggressive, can afford to ignore, and there can be no doubt that public opinion would be utterly against the workings of any labor organization that were engineered from across the border, should trouble arise as a consequence.

The mines of the Dominion Coal Company produced their record output in July, namely, 368,000 tons, which is 18,000 tons more than the previous record, this being the 350,000 tons obtained in October, 1906. This large output was obtained in spite of the fact that the delays experienced were more than the ordinary ones. The output might easily have been 12,000 tons more than it actually was. Nos. 2 and 9 were considerably delayed by the falling of the coal hoisting cage from the top to the bottom of the shaft in the Harbor side, which delayed No. 2 for two days and No. 9 for four days. Up to the end of July the outputs are about 330,000 tons ahead of last year, and the St. Lawrence shipments are about a quarter of a million tons in advance of those of 1907 at this period. When it is remembered that the output of 368,000 tons has been produced on single shift it will be seen how large the capacity of the coal company's mines has become.

The news of the Fernie conflagration has been received here with regret approaching consternation, as so many natives of Nova Scotia are out in the Crow's Pass district. The Cape Breton miner bears the same relation to the Dominion that the Cornish miner bears to the Empire as a whole. He is as ubiquitous as the Nova Scotia seaman. In the Yukon, the Cobalt and the Kootenay one can find the man from "Cape Breton over," and when the early history of Canadian mining comes to be written there will be a fair sprinkling of those Highland names peculiar to Cape Breton.

Sydney.

Mr. E. J. Foster, vice-president of the Great Bras D'Or Gold Mining Company of Middle River, Cape Breton, reports that his company is making satisfactory progress with the development of their mines. The stamp mill is giving pleasing results.

Between the Lizard vein and the footwall a 4-inch vein of nickel-copper ore occurs. It carries 22 per cent. copper and 17 per cent. nickel. This occurrence may prove of economic importance.

Halifax.

The vein of scheelite (calcium) tungstate, which is being opened up near Moose River, Halifax county, averages 50 per cent. tungsten trioxide as mined. It is being actively developed. Search is being carried on for other veins. The discovery is one the importance of which has scarcely been appreciated.

ONTARIO.

Cobalt.

A celebration for the benefit of the Volunteer Fire Department will be held at Cobalt on August 19th and 20th. The most elaborate programme ever attempted in this part of the country has been arranged.

On Wednesday morning, August 19th, a double hand-drilling contest will be held in Cobalt square. A prize of $200 will be given the winning team and $100 to the second. Aquatic sports will be held on Cobalt lake, and in the afternoon a firemans and miners' parade, to be followed by a ball game in Cobalt's new park. Thursday there will be boat, canoe, pointer and swimming races on the lake, and a second ball game in the afternoon. Over $2,000 will be given in prizes. Arrangements have been made with the railroads for special rates from all points.

BRITISH COLUMBIA.

Fernie.

The total loss of the Crow's Nest Pass Company in the recent fire amounts to about $200,000. Very little of the mining plant was damaged. Neither Coal Creek nor Michel was touched by the flames. The timber lands destroyed were valued roughly at $1,000,000. This asset, however, did not appear in the balance sheet of the company and the loss does not affect directly the affairs of the corporation. During the week of the fire the company produced 6,000 tons of coal. Production of both coal and coke will be back at normal figures as soon as sufficient workmen have returned.

A new steel tipple is under construction at Michel and fifty new coke ovens are being built at Fernie and Michel.

The damage done at Hosmer will not delay the commencement of coal and coke shipments in December next. Only ten miners' cottages out of seventy-three were burned. The tipple and trestle are both intact. Two weeks will suffice to clean out the tunnels. The office, bunkhouse and machinery house are undamaged.

Rossland (August).

The mines of this camp continue to produce over 5,000 tons of good ore per week with regularity. The ore is showing up as well as could be expected at depth, especially in the workings of the Consolidated Company's mines, where the main shaft is down on the Centre Star claim over 2,200 feet. Some of the ore taken from the War Eagle-Iron Mask section of this company's property has shown an average value of $31 per ton, which is $18 to $20 higher in value than the average gold-copper ore of this vicinity. The company shipped 2,132 tons of this ore to their smelter at Trail which returned the mine over $27 per ton. Ore of this character is a valuable asset to a mining company in a low-grade belt and comes as a kind of "find," as under existing conditions it costs no more to handle than $10 or $12 ore.

Work is being continued on the small properties around the city and every now and then one of the small mines appears on the shipping list as having sent out a car or two of picked ore. During the week ending July 25th the Sunset was added to the shipping list, the 25-ton car sent out being the first shipment made from the mine for several years.

Things are quite busy about the Trail and Northport smelters and it looks as though business at these places would improve ere long.

The Le Roi 2, Ltd., continues to work ahead and lay up money for another dividend in the impending last few months of the year. The Le Roi 2, Ltd., is certainly making a good showing. A considerable quantity of prospecting work is being done on the ground of this company with an eye to the ore supply of the future. The Vancouver group of claims in the Slocan district, on which the Le Roi 2, Ltd., have expended nearly $100,000, will in future be in the hands of a London flotation known as the Van-Roi Mining Company, the capital stock of which is £34,500. The Le Roi 2, Ltd., will still hold a share in the enterprise in the form of stock.

Boundary.

The latest advice is that the Snowshoe-War Eagle group in Phoenix camp is to resume operations in a few days. This property, controlled by the Consolidated M. & S. Co. of Canada, Ltd., is a valuable copper producer and when once work is going on there then all of the large Boundary copper mines will be in working condition and this district will bear much the appearance of what it has in busy days gone by. The Consolidated Company has expended a considerable sum of money on the Snowshoe group for up-to-date machinery, development work and the acquiring of nearby claims. While the company was only able to operate about nine months of last year, owing to the shortage of coke, etc., yet they managed to mine and ship over 135,000 tons of copper-gold ore. Part of the Snowshoe ore was treated at the Greenwood smelter last year owing to the fact that this smelter was nearer at hand than the company's own smelter at Trail, where but a portion of the output was treated, but it is understood that a majority of this ore will go to Trail when work is commenced, where the ore is desirable as a flux for the "wet" ore received at that point.

The Granby Company has been mining and treating from 20,000 to 22,000 tons of ore per week right along. At this writing four of the furnaces at the Grand Forks smelter of the company are out of commission as they are being connected up to the new blower apparatus. This will, no doubt, cut down the treatment record while the improvements are going on. Owing to the fact that a disastrous fire has ravaged the Fernie district where most of the coke used by the Granby Company is made, it is likely that the supply of that commodity will fall short of the needs of the company and the supply they have on hand at Grand Forks will be used up before things can be got in good running order at the Fernie mines again. If a situation of this character should arise it would probably mean a curtailed output from the Granby mines for a short period.

The B. C. Copper Co. is making several improvements about their mines and smelters, including a new 20,000-volt sub-station to facilitate the transmission of electric power about the works, self-dumping cars, etc. The new Rand compressor is now running without a hitch and as a consequence they have an ample supply of compressed air power about the place for all requirements. An officer of the B. C. Copper Co. has stated that during June the company produced copper and laid it down in New York for 9¾c. per pound, and that during the month of July they would beat this low cost, in consequence of a larger tonnage treated at the same fixed costs. They are shipping a car of blister copper per day.

A strike of marked importance was made on the Dominion Copper Company's Brooklyn mine, Phoenix, a couple of weeks ago. The ore of the Brooklyn mine has been known to carry higher gold values than any of the other Phoenix mines and in the case of the new find the values are up to the standard for this locality. Recent assays give $4.50 in gold, 50c. silver and 2.2 per cent. copper. This ore body has been blocked out on several levels and development work is being executed further to ascertain its exact extent.

The Dominion Copper Company is not shipping what one would call heavily at the present time, but arrangements are being made to equip the two smaller furnaces at Boundary Falls with an up-to-date feed arrangement, when shipments and treatment can be raised to about 1,000 tons per day. They are shipping a quantity of $8 ore from the Athelstan and also a quantity of the Mountain Rose ore, which runs high in iron, for fluxing purposes. Regular shipments are being maintained to the smelter from the Brooklyn, Rawhide and Sunset. The big furnace is treating 650 tons per day.

The ore shipments from the Boundary district for the week ending July 25th were the heaviest that have been recorded for this district so far; 38,113 tons were sent out during the week, running the total for the year to date up to 706,185 tons.

Interest is again being revived in many of the smaller properties in this district and work has been commenced, or will shortly be resumed, on many of them, including the Skylark, Prince Henry, Tip Top, Silver Reef, etc.

Nelson.

Inquires have been made in this vicinity lately in regard to several mining companies that have been organized in this district but which have not achieved very much in the way of definite results. The Maple Leaf Mining Company which was organized here several years ago never did very much in the way of legitimate mining. The promoter, who got a number of business men and some of the clergy interested, was more interested in selling stock than in doing any work on the claim of the company and nearly got himself into trouble with San Francisco shareholders, who sent an engineer to report on the property. The report, we are informed, was not favorable.

Considerable of the stock of the erstwhile Referendum Company, now the Forty-Nine Creek Company, is knocking about the country. Now, the showing on the Referendum as a prospect was quite a promising one. The property is a free milling gold mine and some good looking ore has been taken out of the workings, but there is some doubt as to whether the work has been done in a systematic manner and whether the enterprise will prove to be a mine in the future. There is a 3-stamp mill on the ground and some likely looking gold bricks have been turned out, but taking the thing all in all we would not care to invest our money in a mine of this kind when there are far more promising propositions to be had.

The Fisher Maiden Company were to have resumed operations before this and no doubt will get down to work before long. There is said to be a good showing on this property but in the prospective stage.

It seems almost useless to advise people not to put money into mines that they know nothing about for the fact that they do it is evidenced by the great number of companies throughout this district who are selling stock and doing little or no work other than thinking up brilliant ideas for prospectuses. It would seem that the only way to protect these small investors from themselves would be for the government to adopt some plan limiting the capitalization of mining companies and providing means for seeing that the proceeds of treasury stock were spent on the property and controlling to some extent the selling of promoters' stock, then the investor would know that the money he had paid for treasury stock held by him had all been expended on development and that an effort had at least been made to make his stock more valuable, and the prospect into which he had bought, a mine.

Rossland (July).

The Rossland mines made good headway during the last six weeks and all of the large mines made a good profit on their operations for the month of June. The ore bodies in the lower levels of the Le Roi are developing in good shape and the erstwhile premier mine of the camp is steadily making money. At the Centre Star mines, now the heaviest shipper in Rossland camp, a large amount of $40 ore is still being taken out besides 3,500 to 4,000 tons of average grade ore per week. These mines are now making more money for the Consolidated Company than any of their other holdings. The Consolidated Company has done much for the development of the ore bodies of the southwest side of Red Mountain and at that they have only begun to work. There are large areas in their holdings which have not been explored at all yet and which will not be, even though they are steadily extending their operations, for many years to come. Mining men here expect to see a good annual report from the Consolidated Company for the past fiscal year's work.

Diamond drill exploration still continues on the property of the Le Roi Two, Limited, and the lower levels of this mine look better now than they have ever before; that is, as far as future prospects go. In order to maintain their reputation as Rossland's steady dividend paying mine this company has declared another interim dividend of two shillings per share, paid July 8th. This totals four shillings per share already paid by the Le Roi Two this year, two shillings having been paid to the stockholders in March last. The Le Roi Two, Ltd., is a valuable asset to Rossland camp and it looks as though they would soon be in a position to pay these regular dividends for a good many years yet, the way the ore is coming in at the lower levels.

The work of the lessees hereabouts continues and some good results have been achieved. During the last couple of weeks the Curlew sent out a 30-ton car of good grade ore and the lessees of the Blue Bird shipped a 35-ton car of partly oxidized ore, which is expected to carry exceptionally high values for this district.

The Trail smelter is receiving 6,500 tons of ore per week from Rossland and Slocan districts, about 150 tons per week from the First Thought in Washington and 1,000 tons from the Snow storm in Idaho.

The mining outlook here for this fall is very bright, and as everyone expects copper to go a little higher in the next few months the Rossland mines will no doubt make good profits for the balance of the calendar year.

Boundary.

Things are beginning to look like the good old busy days in the Boundary district. The Granby Company is working away steadily and every day making some improvement in its working plant that will cut down the operating expense. The same may be said of the B. C. Copper Company.

At the Dominion Copper Company mines they have got down to shipping, but the shipments are not as heavy as they will be a little later on, when several important improvements have been made. The big furnace at the Boundary Falls smelter is treating about 650 tons of ore per day, but it is planned to put the two smaller ones in commission as soon as they can be equipped with electric feed, the same as the big one and most of the furnaces now used in this district.

Good news is heard from the Brooklyn property of the Dominion Copper Company, where they have opened up a big new ore body. The values and full extent of this find have not been ascertained at the time of this writing, but it is stated that this lode will have an important bearing on future work at the Brooklyn.

The ore shipments from this district for the week ending July 18th and for the year to date were as follows :

	Week, Tons.	Year, Tons.
Granby Mines	21,744	582,488
Mother Lode (B. C. C. Co.)	8,901	58,015
Oro Denoro (B. C. C. Co.)	2,912	18,558
Brooklyn (D. C. Co.)	1,050	2,220
Rawhide (D. C. Co.)	1,710	4,570
Sunset (D. C. Co.)	576	1,608
Mountain Rose	50	110
Sally	..	80
Crescent	..	50
Snowshoe	..	367

The week's shipments mentioned above were a record lot for this district. The Granby smelter at Grand Forks treated 21,820 tons of ore during the week; the B. C. copper smelter at Greenwood, 13,143 tons, and the Dominion copper smelter at Boundary Falls, 3,625 tons.

As stated above the Dominion Copper Company are fitting up their two small furnaces with electric feed and are to build a 1,200-foot tramway from the Idaho to the Stemwinder to facilitate the handling of ore and reduce the cost of production.

Distinguished visitors to the Boundary from the business centers of the country all express the opinion that conditions will so shape themselves within the next few months that copper will rise to a point near a normal figure. It looks as though the gradually increasing consumption and other factors would bring about this result in the next few months. When the red metal does advance a few cents the copper mines of the Boundary are going to make big profits as they are to-day working on a rock bottom economical basis and many little forms of extravagance that are often overlooked when times are prosperous have been cut off and the little leaks stopped. It is stated that the Granby Company are making copper for between eight and nine cents per pound and at the rate of 30,000,000 pounds per annum.

The work of making a geological survey of Phoenix camp is now under way; the work has begun at the Gold Drop-Snowshoe claims. No doubt this work will prove as valuable to the miners of Phoenix as it has done to those of other districts where surveys have been made.

The stamp mill on the Golden Zone has been completed and will soon be in operation. As is the case in Rossland, Nelson and Ymir districts, in the Similkameen, more development work is being done this year than has been the case for some time past. No extensive development is going on in the Ollala section with the exception of at the Bullion where seven men are at work on active development.

Nelson.
